Abstract

Fixing conformation by introducing a ring structure is a common strategy in drug development. We demonstrate a synthesis that installs a small carbocyclic ring as a structurally-rigid unit in drug lead compounds. Both *trans*- and *cis*-cyclobutane rings were constructed in excellent selectivities by controlling the reaction temperature of an EtAlCl₂-catalyzed [2+2] cycloaddition between a silyl enol ether and an α,β -unsaturated ester. Spirocyclopropane rings were stereospecifically formed by our previously reported ring-contraction rearrangement of fused cyclobutanols. This strategy allowed stereodivergent access to a new class of steroidal derivatives bearing a small ring.

1. Introduction

Rational drug design using protein crystal structures is a rapidly growing area in which several drug discovery success stories have emerged in recent decades. Once the structure of the binding site of the receptor or enzyme is identified, discovery of new small molecule drug leads can be accelerated by using computer simulations such as docking studies. The X-ray crystallographic structure also provides a great opportunity for the optimization of the structure of late-stage leads. For example, the spatial arrangement of the functional groups can be finely tuned at sub-angstrom ($\text{\AA}$) resolution in accordance with the crystallographic structure of the binding site. Conformational fixation of flexible drug leads is a popular tactic used to increase activity and/or reduce side effects. A rotatable side chain on the drug scaffold can be restricted by incorporating a structurally rigid moiety such as a double bond, alkyne, amide or aromatic ring. Small-membered carbocycles such as cyclopropane and cyclobutane rings are also used to restrict rotatable side chains in drug development, owing to their structural rigidity.¹ However, limited numbers of these exist, probably because of the lack of practical and stereoselective synthetic methods.²

We have reported several unique synthetic methods to construct a cyclobutane ring or a spirocyclopropane ring bearing several functional groups with high stereoselectivity. Catalytic [2+2] cycloaddition of readily available silyl enol ethers and α,β -unsaturated esters in the presence of an acid

catalyst, such as EtAlCl_2 and triflic imide (Tf_2NH), affords functionalized cyclobutanes (Scheme 1A).³ The cycloaddition occurs through a stepwise Michael–aldol addition pathway in a diastereoselective manner. A stereospecific ring-contraction rearrangement of fused cyclobutanols to give spirocyclopropanes was also reported (Scheme 1B).⁴ This rearrangement proceeds through a tertiary carbocationic intermediate, which then undergoes rearrangement of the adjacent carbon–carbon bond with release of strain energy.

Scheme 1. Our Methods for Constructing Small Rings

A. Catalytic [2+2] cycloaddition

B. Ring-contraction rearrangement

We envisaged application of this methodology to the stereoselective synthesis of drug derivatives, incorporating a cyclobutane ring or a spirocyclopropane moiety to restrict the conformation. A steroidal

scaffold was chosen as a model drug lead. Steroids are a family of bioactive compounds composed of a unique fused ring system and are widely used as drugs. However, the side effects sometimes become a limiting problem because they have diverse biological activities. For example, calcitriol, which has a steroidal backbone with an opened B-ring, modulates a broad range of biological functions such as bone homeostasis, immunity, cellular growth and differentiation through binding to the vitamin D receptor.⁵ Although synthetic analogues of calcitriol are effective in the treatment of osteoporosis and psoriasis,⁶ their therapeutic use is limited by severe side effects such as hypercalcemia and hypercalciuria.^{5c} Thus, a number of calcitriol analogues have been synthesized to discover which ones display biological activities and reduced side effects better than natural steroid hormones.^{5c,7} Mouriño reported calcitriol analogues with a locked side chain by introducing an unsaturated bond or an additional ring.⁸ Some of the analogues exhibited significant biological activities, such as the induction of the transcriptional activity of vitamin D receptors in human colon cancer cells.^{8c} Herein, we report a stereodivergent synthesis of steroidal derivatives bearing a small ring using a [2+2] cycloaddition and stereospecific ring-contraction rearrangement. During the course of our synthetic study, switching the diastereoselectivity of the [2+2] cycloaddition depending on the reaction temperature was observed. The mechanistic insight of this is also discussed.⁹

2. Results and discussion

At the outset of the study, the [2+2] cycloaddition of silyl enol ether **1**, prepared from estrone 3-methyl ether, with methyl acrylate (**2a**) was investigated (Table 1). When silyl enol ether **1** was treated with 1.3 equivalents of **2a** at $-78\text{ }^{\circ}\text{C}$ in the presence of 1.0 mol% of $\text{ Tf}_2\text{NH}$, cyclobutane *cis*-**3a** was afforded in only 5% yield (entry 1). There was a decrease or slight increase in yield when using more equivalents of $\text{ Tf}_2\text{NH}$ and methyl acrylate (entries 2–4). Reaction with 1,1,3,3-tetrakis(triflyl)propane ($\text{ Tf}_2\text{CHCH}_2\text{CHTf}_2$)¹⁰ resulted in no significant improvement in yield (entry 5), whereas EtAlCl_2 was an effective catalyst and afforded *cis*-**3a** in 77% yield (entry 6).

Interestingly, when using hexafluoroisopropyl (HFIP) acrylate (**2b**) instead of **2a**, we observed that the diastereoselectivity in the [2+2] cycloaddition switched depending on the reaction conditions (Table 2). Treatment of silyl enol ether **1** with **2b** in the presence of EtAlCl₂ at −78 °C produced *trans*-**3b** in 85% yield with high diastereoselectivity (entry 1). The *trans*-selectivity remained approximately constant regardless of the reaction time (entries 1 and 2). In contrast, the *trans*-selectivity of **3b** decreased with an increase in reaction temperature (entries 1, 3–5). When the reaction was carried out at room temperature, *cis*-**3b** was obtained exclusively in 74% yield along with 12% yield of the Michael adduct **4** (entry 5). The reaction conducted at −78 °C for 10 min, followed by stirring at room temperature for an additional 10 min, afforded only the *cis*-adduct (entry 6). The results clearly indicate that *trans*-**3b** is the kinetically favored product whereas *cis*-**3b** is the thermodynamically more stable one. Reactions with methyl acrylate (**2a**) at both room temperature (rt) and −78 °C afforded *cis*-**3a** exclusively (entry 8 and Table 1 entry 6). Even when the reaction temperature was lowered to −90 °C, *trans*-**3a** was obtained only as a minor diastereomer (entry 7). It appears that the activation energy required for isomerization of *trans*-**3** to *cis*-**3** is dependent on the ester substituent.

^a Isolated yields. ^b Michael adduct **4** was obtained in 5–12 % yield.

Crossover experiments were performed to investigate the diastereoselectivity switch further.

Treatment of *trans*-**3b** with EtAlCl₂ at ambient temperature resulted in complete conversion into *cis*-**3b**

(Scheme 2, eq 1), whereas no reaction occurred in the absence of EtAlCl₂. Using the same catalyst at the same temperature, *cis*-**3b** did not isomerize to *trans*-**3b**. When a mixture of the methyl ester *cis*-**3a** and an equimolar of HFIP acrylate (**2b**) was treated with EtAlCl₂ at ambient temperature, the crossover adduct *cis*-**3b** was afforded in 35% yield as a single diastereomer, along with 35% yield of recovered *cis*-**3a** (eq 2). These results indicate that EtAlCl₂ promotes the retro [2+2] process to reproduce silyl enol ether **1** and acrylate **2**. HFIP acrylate (**2b**) competes with *in situ* generated methyl acrylate (**2a**) in the [2+2] cycloaddition of the regenerated silyl enol ether **1**, which results in the isolation of a mixture of *cis*-**3a** and *cis*-**3b**. In contrast, the reaction of methyl ester *cis*-**3a** at −40 °C did not provide the crossover adduct, but rather the ring-opened product **4a** in 30% yield (eq 3). In the reaction of a mixture of *trans*- and *cis*-**3a** at −40 °C, epimerization of *trans*-**3a** into *cis*-**3a** occurred along with the formation of **4a**, but no crossover product was observed (eq 4).

Scheme 2. Mechanistic Insights into the EtAlCl₂-Catalyzed [2+2] Cycloaddition

Based on the above results, a possible mechanism for the EtAlCl_2 -catalyzed [2+2] cycloaddition of **1** is shown in Figure 1. Michael addition of silyl enol ether **1** to acrylate **2** proceeds predominantly at the less hindered α -face to give zwitterionic intermediate **5**. At lower temperatures, intramolecular aldol-type addition of **5** takes place via the preferred transition state **TS-I** to give *trans*-**3**, whereas less favored **TS-II** affords *cis*-**3** because of steric effects. The product *trans*-**3** would be less stable than *cis*-**3** because of steric repulsion between the axial hydrogen atom at the C14 position and the ester moiety, which is supported by DFT calculations of *cis*- and *trans*-**3b** ($\Delta G^\circ_{\text{cis-trans}} = -12.6 \text{ kJ/mol}$).¹¹ The epimerization process is rather

complicated. At ambient temperature, *trans*- and *cis*-**3** equilibrate through a retro [2+2] cycloaddition via silyl enol ether **1** to provide the thermodynamically more stable *cis*-**3**. In contrast, the retro [2+2] cycloaddition does not proceed at $-40\text{ }^{\circ}\text{C}$, which indicates that the epimerization to *cis*-**3** at this temperature occurs via siloxonium ion **5** through a retro aldol reaction. In addition, ketone **4** was presumably formed by desilylation of ketene silyl acetal **6** during work-up.

Figure 1. Possible Mechanism for the EtAlCl_2 -Catalyzed [2+2] Cycloaddition under Kinetic and Thermodynamic Conditions

With the cyclobutane scaffolds constructed, we next investigated the ring-contraction rearrangement of cyclobutanols to give spirocyclopropanes (Scheme 3). To prepare the substrate for the ring-contraction rearrangement, *trans*-**3b** was treated with Red-Al to afford cyclobutanol *trans*-**7** in 89% yield. Removal of the *tert*-butyldimethylsilyl (TBS) group on the tertiary hydroxyl function followed by benzoyl protection of the primary hydroxyl group furnished *trans*-**9**. *Cis*-**9** was also prepared through the same procedure from *cis*-**3b**. With the substrates **9** for the ring contraction reaction in hands, the reaction

conditions was firstly screened by using *cis*-**9**. According as our previous conditions,⁴ *cis*-**9** was treated with methanesulfonyl chloride (MsCl) in 2,6-lutidine, which resulted in the formation of the mesylated product (*ca.* 30%), along with recovered starting material (*ca.* 40%). We tried other conditions such as oxalyl chloride/triethylamine and triflic anhydride/triethylamine to convert the tertiary hydroxyl group to a good leaving group; however, these attempts proved unsuccessful, and no spirocyclopropane product was observed. The ring contraction rearrangement of *cis*-**9** was finally achieved by using thionyl chloride/triethylamine to afford (20*S*)-**10** in 87% yield ($16\beta:16\alpha = 4:1$), the relative configuration was determined by the NOE Spectroscopy. The same conditions were successfully applied to the rearrangement of *trans*-**9** to afford (20*R*)-**10** in a stereospecific manner, albeit in lower yield (66%, $16\beta:16\alpha = 7:3$). In these reactions, the carbocationic intermediates predominantly undergo nucleophilic attack by the chloride ion to afford (20*S*)- or (20*R*)-**10**, and no elimination products are observed. The difference in yield between (20*S*)- and (20*R*)-**10** was due to the formation of byproduct **11**. We do not fully understand why the ring-contraction rearrangement of *trans*-**9** yielded this unusual product, but it may be influenced by the dihedral angle between the migrating carbon–carbon bond and the empty p-orbital of the carbocationic intermediate.

Scheme 3. Construction of a Spirocyclopropane Ring by Ring-Contraction Rearrangement

With the estrone derivatives bearing a small ring in hand, our attention turned toward the installation of a cholestane side chain (Scheme 4). Initially, removal of the benzoyl group and dechlorination of *(20S)*-**10** were performed in one-pot using Red-Al to give cyclopropanol *(20S)*-**12**, which was then subjected to Swern oxidation to afford aldehyde *(20S)*-**13**. Extension of the carbon chain was accomplished by one-pot Julia olefination of the aldehyde using benzothiazolyl sulfone **15**, which was prepared from 3-methyl-1,3-butanediol in five steps (Scheme 5). Triethylsilyl (TES) protection of **15** was necessary for complete conversion of the starting aldehydes in the olefination reactions. Reduction of olefin **16** was unsuccessfully attempted by hydrogenation using Pd/C in ethyl acetate, which resulted in simultaneous ring-opening of the cyclopropane. Accordingly, several catalysts were tested for the chemoselective

hydrogenation. Reduction with Pd/Fib or Pd/C(en) gave a cyclopropane ring-opened product with the intact carbon–carbon double bond. No reaction occurred using Pd/MS5A¹³ or Pd/BN¹⁴ in methanol. In the reaction with Rh/alumina in ethyl acetate, the double bond was reduced without ring-opening of the cyclopropane, but the aromatic A-ring was also reduced to a cyclohexane ring. Although these efforts using heterogeneous catalysts were unfruitful, chemoselective reduction of the olefin was achieved by diimide reduction,¹⁵ which was followed by removal of the TES group to give (20*S*)-**17**. The final deprotection of the methyl group was troublesome. Treatment with BBr₃ or reagents such as TMSI, NaSEt, or AlMe₃/NaI¹⁶ gave a complex mixture, probably due to instability of the spirocyclopropane. Nevertheless, the deprotection was accomplished by using *n*-BuLi/PPh₂H¹⁷ to give the final product (20*S*)-**18** in 76% yield. (20*R*)-**18** was also synthesized by the similar procedure. It is worth noting that treatment of (20*R*)-**10** with Red-Al gave a considerable amount of byproducts. Reduction with sodium borohydride in DMSO at 130 °C gave (20*R*)-**12** in 53% yield with less byproduct formation.¹²

Scheme 5. Preparation of Benzothiazolyl Sulfone **15**

Installation of the side chain onto the cyclobutane ring was also accomplished using a similar strategy (Scheme 6). Swern oxidation followed by one-pot Julia olefination of *trans*- and *cis*-**7** afforded cyclobutanes *trans*- and *cis*-**19**, respectively. Reduction of the resulting olefin and removal of the TES group were carried out in one-pot by hydrogenation with palladium on carbon. Cleavage of the methyl and TBS groups completed the synthesis of *trans*- and *cis*-**22**, and the structures were verified by X-ray crystallography.

3. Conclusion

We have demonstrated the synthesis of four cholestane-type steroidal compounds bearing a cyclobutane or a spirocyclopropane skeleton. The described route features a diastereo-switchable [2+2] cycloaddition reaction and a stereospecific ring-contraction to construct small rings in a stereo-divergent manner. The diastereoselectivity in the [2+2] cycloaddition was inverted under kinetic or thermodynamic conditions. A carbon side chain was installed on the small rings using a one-pot Julia olefination followed by reduction of

the resulting olefin. This strategy provides a facile route to access a new class of steroid derivatives bearing a small ring. Biological evaluation of the synthetic steroids is currently underway.

4. Experimental Section

4.1. General Remarks

All non-aqueous reactions were carried out under a positive atmosphere of argon in dried glassware. Dehydrated solvents were purchased for the reactions and used without further desiccation. Reagents were purchased and used without further purification, unless otherwise stated. Reactions were monitored by thin-layer chromatography (TLC) carried out on Merck TLC silica gel 60 F₂₅₄. Column chromatography was performed using Fuji Silysia BW-200 silica gel. Nuclear magnetic resonance (NMR) spectra were recorded on a JEOL JNM-ECA 500 instrument. The ¹H chemical shifts were calibrated with internal tetramethylsilane (TMS, 0 ppm) in deuterated organic solvents. The ¹³C chemical shifts are reported relative to CDCl₃ (77.0 ppm), DMSO-*d*₆ (39.5 ppm), acetone-*d*₆ (206.7 and 30.4 ppm), MeOH-*d*₄ (49.0 ppm) or THF-*d*₈ (67.4 and 25.3 ppm). The following abbreviations were used to explain NMR peak multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad. Low-resolution mass spectra (LRMS) were recorded on a SHIMADZU GCMS-QP2010 SE spectrometer (EI) or a JEOL MS700 spectrometer (FAB).

High-resolution mass spectra (HRMS) were recorded on a JEOL MS700 spectrometer (FAB) or a SHIMADZU LCMS-IT-TOF fitted with an ESI. IR experiments were recorded on a SHIMADZU IRAffinity-1 spectrometer. The wave numbers of maximum absorption peaks of IR spectroscopy are presented in cm^{-1} . All melting points were determined using a Yamato MP-21 melting point apparatus and are uncorrected. Optical rotations were obtained on a JASCO P-1030 polarimeter. X-ray diffraction data were recorded on a RIGAKU R-Axis RAPID system. Compounds **1**,⁹ *cis*-**3a**,⁹ *trans*-**3b**,⁹ *cis*-**3b**,⁹ **4a**⁹ and dipotassium azodicarboxylate¹⁸ were prepared according to previous procedures.
