Abstract

The unification problem for term rewriting systems (TRSs) is the problem of deciding, for a TRS $R$ and two terms $s$ and $t$, whether $s$ and $t$ are unifiable modulo $R$. Mitsuhashi et al. have shown that the problem is decidable for confluent simple TRSs. Here, a TRS is simple if the right-hand side of every rewrite rule is a ground term or a variable. In this paper, we extend this result and show that the unification problem for confluent semi-constructor TRSs is decidable. Here, a semi-constructor TRS is such a TRS that every subterm of the right-hand side of each rewrite rule is ground if its root is a defined symbol. We first show the decidability of joinability for confluent semi-constructor TRSs. Then, using the decision algorithm for joinability, we obtain a unification algorithm for confluent semi-constructor TRSs.

1 Introduction

The unification problem for term rewriting systems (TRSs) is the problem of deciding, for a TRS $R$ and two terms $s$ and $t$, whether $s$ and $t$ are unifiable modulo $R$. This problem is undecidable in general and even if we restrict to either right-ground TRSs [9] or terminating, confluent, monadic, and linear TRSs [7]. Here, a TRS is monadic if the height of the right-hand side of every rewrite rule is at most one [12]. On the other hand, it is known that unification is decidable for some subclasses of TRSs [2, 4, 5, 8, 11]. Recently, Mitsuhashi et al. have shown that the unification problem is decidable for confluent simple TRSs [7]. Here, a TRS is simple if the right-hand side of every rewrite rule is a ground term or a variable. In this paper, we extend the result of [7] and show that unification for confluent semi-constructor TRSs is decidable. Here, a semi-constructor TRS is such a TRS that every subterm of the right-hand side of each rewrite rule is ground if its root is a defined symbol.

In order to obtain this result, we first show the decidability of joinability for confluent semi-constructor TRSs. Joinability of several subclasses of TRSs has been shown to be decidable so far [13]. Many of these decidability results have been proved by reducing these problems to decidable ones for tree automata, so that these decidable subclasses are restricted to those of right-linear TRSs. In this paper, we provide a decidability result of joinability for possibly non-right-linear TRSs. To our knowledge, such attempts were very few so far.

Moreover, in this paper we show that confluence is necessary to show the decidability of joinability for semi-constructor TRSs, that is, joinability for (non-confluent) linear semi-constructor TRSs is undecidable.

2 Preliminaries

We assume that the reader is familiar with standard definitions of rewrite systems (see [1, 14]) and we just recall here the main notions used in this paper.

Let $X$ be a set of variables, $F$ a finite set of operation symbols graded by an arity function $\text{ar}: F \rightarrow \mathbb{N}$, $F_n = \{ f \in F \mid \text{ar}(f) = n \}$, $\text{Leaf} = X \cup F_0$, the set of leaf symbols, and $T$ the set of terms constructed from $X$ and $F$. We use $x, y, z$ as variables, $b, c, d$ as constants, and $r, s, t$ as terms. A term is ground if it has no variable. Let $G$ be the set of ground terms and let $S = T \setminus (G \cup X)$. Let $V(s)$ be the set of variables occurring in $s$. The height of $s$ is defined as follows: $h(a) = 0$ if $a$ is a leaf symbol and
The root symbol is defined as \( \text{root}(a) = a \) if \( a \) is a leaf symbol and \( \text{root}(f(t_1, \ldots, t_n)) = f \).

A position in a term is expressed by a sequence of positive integers, which are partially ordered by the prefix ordering \( \leq \). To denote that positions \( u \) and \( v \) are disjoint, we use \( u \cap v \). The subset of all minimal positions (w.r.t. \( \leq \)) of \( W \) is denoted by \( \text{Min}(W) \). Let \( \mathcal{O}(s) \) be the set of positions of \( s \).

Let \( s_{tu} \) be the subterm of \( s \) at position \( u \). We use \( s[t]_u \) to denote the term obtained from \( s \) by replacing the subterm \( s_{tu} \) by \( t \). For a sequence \( (u_1, \ldots, u_n) \) of pairwise disjoint positions and terms \( r_1, \ldots, r_n \), we use \( s[r_1, \ldots, r_n](u_1, \ldots, u_n) \) to denote the term obtained from \( s \) by replacing each subterm \( s_{tu} \) by \( r_i \) (1 \( \leq i \leq n \)).

A rewrite rule is defined as a directed equation \( \alpha \rightarrow \beta \) that satisfies \( \alpha \not\in X \) and \( V(\alpha) \supseteq V(\beta) \). Let \( \leftarrow \) be the inverse of \( \rightarrow \). Let \( \gamma: s_1 \rightarrow^* s_n \) be a rewrite sequence. This sequence is abbreviated to \( \gamma: s_1 \rightarrow^* s_n \) and \( \mathcal{R}(\gamma) = \{u_1, \ldots, u_{n-1}\} \) is the set of the redex positions of \( \gamma \). If the root position \( e \) is not a redex position of \( \gamma \), then \( \gamma \) is called \( e \)-invariant. For any sequence \( \gamma \) and position set \( W \), \( \mathcal{R}(\gamma) \supseteq W \) if for any \( v \in \mathcal{R}(\gamma) \) there exists \( a \in W \) such that \( v \geq u \). If \( \mathcal{R}(\gamma) \supseteq W, \) we write \( \gamma: s_1 \rightarrow^* s_n \).

Let \( \mathcal{O}_\alpha(s) = \{ u \in \mathcal{O}(s) \mid s_{tu} \in \mathcal{G} \} \). For any set \( \Delta \subseteq X \cup F \), let \( \mathcal{O}_\Delta(s) = \{ u \in \mathcal{O}(s) \mid \text{root}(s_{tu}) \in \Delta \} \). Let \( \mathcal{O}_C(s) = \mathcal{O}_{\{s\}}(s) \). The set \( D \) of defined symbols for a TRS \( R \) is defined as \( D = \{ \text{root}(\alpha) \mid \alpha \rightarrow \beta \in R \} \).

A term \( s \) is semi-constructor if, for every subterm \( t \) of \( s \) such that \( \text{root}(t) \) is defined, \( t \) is ground.

### Definition 1
A rule \( \alpha \rightarrow \beta \) is ground if \( \alpha, \beta \in G \), right-ground if \( \beta \in G \), semi-constructor if \( \beta \) is semi-constructor, and linear if \( |\mathcal{O}_\alpha(\alpha)| \leq 1 \) and \( |\mathcal{O}_\alpha(\alpha)| \leq 1 \) for every \( x \in X \).

### Example 2
Let \( R_e = \{ \text{and}(x, x) \rightarrow \text{not}(x), \text{and}(\text{not}(x), x) \rightarrow t, t \rightarrow \text{nand}(f, f), f \rightarrow \text{nand}(t, t) \} \).

\( R_e \) is semi-constructor, non-terminating and confluent [3]. We will use this \( R_e \) in examples given in Section 3.

### Definition 3
[11] A rewrite rule is an ordered pair of terms \( s \) and \( t \), with \( s \approx t \), such that \( \alpha \rightarrow^* \beta \). Such \( \alpha \) and \( \beta \) are called an \( R \)-unifier and a proof of \( s \approx t \), respectively. This notion is extended to sets of term pairs: for \( \Gamma \subseteq T \times T \), \( \beta \) is an \( R \)-unifier of \( \Gamma \) if \( \beta \) is an \( R \)-unifier of every pair in \( \Gamma \). In this case, \( \Gamma \) is \( R \)-unifiable. As a special case of \( R \)-unifiability, \( s \approx t \) is 0-unifiable if there exists a substitution \( \theta \) such that \( \beta \theta = \theta \), i.e., 0-unifiability coincides with the usual unifiability. If \( s \downarrow t \) then \( s \approx t \) is joinable.

### Definition 4
TRSs \( R \) and \( R' \) are equivalent if \( \rightarrow^*_R = \rightarrow^*_{R'} \).

## 3 Joinability

First, we show that the joinability and reachability problems for (non-confluent) semi-constructor TRSs are undecidable.

### Theorem 5
The joinability and reachability problems for linear semi-constructor term rewriting systems are undecidable. Proof [sketch] The proof is by a reduction from the Post's correspondence problem (PCP). Let \( P = \{ (u_i, v_i) \in \Sigma^* \times \Sigma^* \mid 1 \leq i \leq k \} \) be an instance of the PCP. The corresponding TRS \( R_P \) is constructed as follows: Let \( F_0 = \{ c, d, \$ \}, F_1 = \Sigma \cup \{ f, h \}, F_2 = \{ g \}, R_P = \{ c \rightarrow h(c), c \rightarrow d, d \rightarrow f(d), g(u(\$), v(\$)), f(g(x, y)) \rightarrow g(u(x), v(y)) \mid 1 \leq i \leq k \} \cup \{ g(a(x), a(y)) \rightarrow g(x, y) \mid a \in \Sigma \} \). \( u(x) \) is an abbreviation for \( a_1(a_2(\cdots a_k(x))) \) where \( a_1, a_2, \ldots a_k \) with \( a_1, \ldots, a_k \in \Sigma \). \( R_P \) is linear and semi-constructor. For \( R_P \), the following three propositions (1)–(3) are equivalent: (1) \( c \downarrow g(\$, \$) \), (2) \( c \rightarrow^* g(\$, \$) \), and (3) PCP \( P \) has a solution.

### 3.1 Standard Semi-Constructor TRSs

From now on, we consider only confluent semi-constructor TRSs, for which joinability is shown to be decidable. In order to facilitate the decidability proof, we transform a TRS into a simpler equivalent one.

### Definition 6
For TRS \( R \), we use \( R_{RG} \) and \( R_{NRG} \) to denote the sets of right-ground and non-right-ground rewrite rules in \( R \), respectively.
If $R$ is clear from the context, we write $\rightarrow_{Rg}$ instead of $\rightarrow_{Rg}$.

**Definition 7** A TRS $R$ is **standard** if the following condition holds: for every $\alpha \rightarrow \beta \in R$ either $\alpha \in F_0$ and $h(\beta) \leq 1$ or $\alpha \notin F_0$ and for every $u \in \mathcal{O}(\beta)$ if $\beta_u \in G$ then $\beta_u \in F_0$.

Let $R_0$ be a confluent semi-constructor TRS. The corresponding standard TRS $R^{(1)}$ is constructed as follows. First, we choose $\alpha \rightarrow \beta \in R_k (k \geq 0)$ that does not satisfy the standardness condition. If $\alpha \in F_0$ then let $\{u_1, \ldots, u_m\} = \text{Min}(O_G(\beta) \setminus O_{R_0}(\beta))$. Let $R_{k+1} = R_k \setminus \{\alpha \rightarrow \beta\} \cup \{\alpha \rightarrow \beta[d_1, \ldots, d_m | u_1, \ldots, u_m] \in \text{Min}(O_{R_0}(\beta)) \}$. This procedure is applied repeatedly until the TRS satisfies the condition of standardness. The resulting TRS is denoted by $R^{(1)}$. For example, \{$(f_1(x) \rightarrow g(x, g(a, b))), f_2(x) \rightarrow f_2(g(c, d))$\} is transformed to \{$(f_1(x) \rightarrow g(x, d_1), d_1 \rightarrow g(a, b), f_2(x) \rightarrow d_2, d_2 \rightarrow f_2(d_3), d_3 \rightarrow g(c, d))$\}. This transformation preserves confluence, joinability and unifiability.

**Lemma 8**

1. $R^{(1)}$ is confluent.
2. For any terms $s, t$ which do not contain new constants, $s \downarrow_{R_0} t$ iff $s \downarrow_{R^{(1)}} t$.
3. For any terms $s, t$ which do not contain new constants, $s \approx t$ is $R_0$-unifiable iff $s \approx t$ is $R^{(1)}$-unifiable.

The proof is straightforward, since $R_0$ is confluent. By this lemma, we can assume that a given confluent semi-constructor TRS is standardized without loss of generality. By standardization, for any $\alpha \rightarrow \beta \in R_{Rg}$, $\alpha \in F_0$ or $\beta \in F_0$ holds and $h(\beta) \leq 1$. However, by the transformation algorithm given in Section 3.2, the heights of the right-hand sides of ground rules (called $R_C$ type rules later) may increase. This is the only exceptional case.

### 3.2 Adding Ground Rules

The joinability for right-ground TRSs is decidable [10]. In this paper, we show that the joinability for confluent semi-constructor TRSs is decidable, by reducing to the joinability for right-ground TRSs.

Let $R_1$ be a confluent TRS and $R_2$ be such a TRS that $\rightarrow_{R_2} \subseteq \rightarrow_{R_1}$. Then, obviously $R_1 \cup R_2$ is equivalent to $R_1$ and confluent. Thus, even if we add pairs of joinable terms of $R_1$ to $R_1$ as new rewrite rules (called shortcuts), confluence, joinability and unifiability properties are preserved. Note that reachability is not necessarily preserved. Now, we show that the joinability of confluent semi-constructor TRSs reduces to that of right-ground TRSs by adding new finite ground rules. For this purpose, we need some definitions.

**Definition 9** A rule $\alpha \rightarrow \beta$ has **type C** if $\alpha \in F_0, \beta \notin F_0$ and $\mathcal{O}(\alpha) \setminus \mathcal{O}(\beta) = \emptyset$, and has **type F** if $\alpha, \beta \in F_0$.

Let $R_C = \{\alpha \rightarrow \beta \in R | \alpha \rightarrow \beta \text{ has type } \tau\}$. That is, $R_C$ is the subset of $R_{Rg}$ satisfying that for every rule $\alpha \rightarrow \beta \in R_C$, $\alpha$ is a constant, and $\beta$ is non-constant and contains no defined non-constant symbol. Henceforth, we assume that $R \setminus R_C$ is standard.

**Definition 10**

\[
\text{hd}(s) = \begin{cases} 
    w + \max\{\text{hd}(s_i) | 1 \leq i \leq n\} & \text{if } s = f(s_1, \ldots, s_n), n > 0, f \in D \\
    1 + \max\{\text{hd}(s_i) | 1 \leq i \leq n\} & \text{if } s = f(s_1, \ldots, s_n), n > 0, f \notin D \\
    0 & \text{if } s = \text{Leaf}
\end{cases}
\]

where $w = 1 + 2 \max\{h(\beta) | \alpha \rightarrow \beta \in R\}$. Note that we give weight $w$ to each defined non-constant symbol and 1 to each other non-constant symbol and define new heights derived from these weights. We define $\text{hd}(s) = \{\text{hd}(s_i) | u \in \mathcal{O}(s)\}_m$, which is a multiset of heights of all subterms of $s$. Here, we use $\{\cdots\}_m$ to denote a multiset and $\cup$ to denote multiset union. For TRS $R_{\text{ex}}$ of Example 1, $w = 3$ and $\text{hd}(\text{nand}(\text{not}(x), x)) = \{0, 0, 1, 4\}_m$.

Let $\ll$ be the multiset extension of the usual relation $< \ll$ on $N$ and let $\ll = \ll \cup =$. Let $\#(s) = (\text{hd}(s), g(s))$. Here, function $g(s)$ returns a natural number corresponding to $s$ uniquely, and we assume that the ordering derived by this function is closed under context, i.e., for any terms $r, s, t$ and any position $u \in \mathcal{O}(r)$, if $g(s) < g(t)$ then $g(r[s/u]) < g(r[t/u])$. Such a function $g$ is effectively computable. In order to compare $\#(s)$ and $\#(t)$, we use lexicographic order $<_{\text{lex}}$. Note that $<_{\text{lex}}$ is a total order. A term $s_0$ is minimum in set $\Delta$ iff $s_0 \in \Delta$ and $\#(s_0) = \min\{\#(s') | s' \in \Delta\}$.
Definition 11

(1) Function \(\text{linearize}(s)\) linearizes non-linear term \(s\) in the following manner. For each variable occurring more than once in \(s\), the first occurrence is not renamed, and the other ones are replaced by new pairwise distinct variables. For example, \(\text{linearize}(\text{nand}(x, x)) = \text{nand}(x, x_1)\). If function linearize replaces \(x\) by \(x_1\), then we use \(x \equiv x_1\) to denote the replacement relation.

(2) For set \(\Delta \subseteq T\), \(\text{Psub}(\Delta) = \{s_{iu} \mid s \in \Delta, u \in O(s) \setminus \{e\}\}\).

(3) For set \(\Delta \subseteq T\), \(\text{Bud}(\Delta, R_C) = F_0 \cup \text{Psub}(\Delta \cup \{\beta \mid \alpha \rightarrow \beta \in R_C\})\). Note that if \(\Delta \subseteq F_0\) then \(\text{Bud}(\Delta, R_C) = \text{Bud}(\emptyset, R_C)\).

(4) Substitution \(\sigma\) is joinability preserving under relation \(\equiv\) for \(\text{TRS} R_{rg}\) if \(s \rightarrow_{R_{rg}} x'\sigma\) whenever \(x \equiv x'\). In this case, we write \(\sigma \in \downarrow(\equiv, R_{rg})\).

(5) For \(\text{TRS} R\) and term \(\alpha\), \(R(\alpha) = \{\beta \mid \alpha \rightarrow \beta \in R\}\).

(6) Let \(\{s_1, \ldots, s_m\} = R_C(d)\) and \(\{u_1, \ldots, u_n\} = \text{Min}(\bigcup_{1 \leq i \leq m} O_F(s_i))\). Let \(d_j\) be the minimum term in \(\{s_{i|u_j} \mid 1 \leq i \leq m, 1 \leq j \leq n\}\). Then we define \(\text{Normalize}(d, R_C) = \{d \rightarrow s_{i|u_j} \mid 1 \leq i \leq m, 1 \leq j \leq n, d_j \neq s_{i|u_j}\}\). For example, \(\text{Normalize}(\{t \rightarrow \text{not}(\text{not}(t)), t \rightarrow \text{not}(t)\}) = \{t \rightarrow \text{not}(t), \text{not}(t)\}\).

Lemma 12 Let \(R \setminus R_C\) be standard. Let \(\alpha \rightarrow \beta \in R_{rg}\), \(\theta : X \rightarrow T\) and \(s \rightarrow_{R_{rg}} a\theta\). Let \(\alpha' = \text{linearize}(\alpha)\). Then, there exists a substitution \(\sigma : V(\alpha') \rightarrow \text{Bud}((s), R_C)\) such that \(s \rightarrow_{R_{rg}} \alpha'\sigma \rightarrow_{R_{rg}} a\theta, \beta\sigma \rightarrow_{R_{rg}} \beta\theta\) and \(\sigma \in \downarrow(\equiv, R_{rg})\).

By Lemma 12, for a rewrite sequence \(d \rightarrow_{R_{rg}} a\theta \rightarrow \beta\theta\), there exists \(a\sigma\) such that \(d \rightarrow_{R_{rg}} a\sigma \rightarrow_{R_{rg}} a\theta, \beta\sigma \rightarrow_{R_{rg}} \beta\theta\). So, if we add a new ground rule \(d \rightarrow \beta\sigma\) to \(R\), then we have \(d \rightarrow_{R'} \beta\sigma\) for \(R' = R_{rg} \cup \{d \rightarrow \beta\sigma\}\). Thus, by adding shortcut rules such as \(d \rightarrow \beta\sigma\), we can omit applications of \(\alpha \rightarrow \beta\) which is a non-right-ground rule. Using this technique, the following algorithm takes as input a standard semi-construct \(\text{TRS} R^{(0)}\) and produces as output an equivalent semi-construct \(\text{TRS} R^{(f)}\) satisfying that if \(d \rightarrow_{R^{(0)}} s\) then \(d \rightarrow_{R^{(f)}} s\). We call \(R^{(f)}\) a quasi-right-ground \(\text{TRS}\), hereafter.

```plaintext
function MakeQuasiRightGround(R)
  R := Determineize(R);
  repeat
    R' := R;
    R := Determineize(AddShortcuts(R'))
  until R = R';
  return R;

function AddShortcuts(R)
  R' := R;
  for each \(\alpha \rightarrow \beta \in R_{rg}\) do
    \(\alpha' := \text{linearize}(\alpha)\);
    for each \(d \in F_0, \sigma : V(\alpha') \rightarrow \text{Bud}(\emptyset, R_C)\) such that \(\sigma \in \downarrow(\equiv, R_{rg})\) do
      if \(d \rightarrow_{R_{rg}} a\sigma\) then \(R' := R' \cup \{d \rightarrow \beta\sigma\}\)
  return R';

function Determineize(R)
  while there exists \(d\) such that \(|R_C(d)| > 1\) do
    R := R \cup \text{Normalize}(d, R_C) \setminus \{d \rightarrow s \mid d \rightarrow s \in R_C\}
  return R;
```

Example 13 For \(\text{TRS} R_e\) of Example 1, \(\text{MakeQuasiRightGround}(R_e)\) first computes \(\text{Determineize}(R_e)\). It returns the same \(R_e\) as output. Next, \(\text{AddShortcuts}(R_e)\) is called. Since \(t \rightarrow \text{nand}(f, t), \text{nand}(x, x) \rightarrow \text{not}(x) \in R_e\), a new shortcut rule \(t \rightarrow \text{not}(f)\) is added to \(R_e\). Similarly, \(f \rightarrow \text{not}(t)\) is added. Thus, \(\text{AddShortcuts}(R_e) = R'\) where \(R' = R_e \cup \{t \rightarrow \text{not}(f), f \rightarrow \text{not}(t)\}\). Next, \(\text{Determineize}(R')\) is called and
returns the same \( R' \) as output. Then, \( \text{AddShortcuts}(R') \) is called. Note that \( R'_C = \{ t \rightarrow \text{not}(f), f \rightarrow \text{not}(t) \} \). \( \text{AddShortcuts}(R') \) returns the same \( R' \) and also calls \( \text{Determinize}(R') \). Then, the algorithm halts. Let \( R''_C \) be this result: \( R''_C = R'_C \cup \{ t \rightarrow \text{not}(f), f \rightarrow \text{not}(t) \} \), which will be used in later examples.

We apply this algorithm to standard TRS. But by an application of this algorithm, the heights of some right-hand side terms of type \( C \) rules may become greater than 1. This algorithm satisfies the following lemmata.

**Lemma 14** MakeQuasiRightGround is terminating.

**Lemma 15** Let \( R^{(i)} = \text{MakeQuasiRightGround}(R^{(i)}) \).

1. If \( d \rightarrow_{R^{(i)}}^* s \) then \( d \rightarrow_{R^{(i)}} s \).
2. \( \rightarrow_{R^{(i)}} \subseteq \downarrow_{R^{(i)}} \).

**Corollary 16**

1. \( R^{(i)} \) is confluent (since \( R^{(i)} \) is confluent).
2. \( c \downarrow_{R^{(i)}} d \iff C \downarrow_{R^{(i)}} \).
3. \( s \approx t \) is \( R^{(i)} \)-unifiable iff \( s \approx t \) is \( R^{(i)} \)-unifiable.

### 3.3 Auxiliary Terms

We have shown that all rewrite sequences from every constant in \( R^{(i)} \) (i.e., \( d \rightarrow_{R^{(i)}}^* s \)) can be obtained by using only right-ground rules (i.e., \( d \rightarrow_{R^{(i)}}^* s \)). Now, we want to extend this result to that for rewrite sequences from any term. For this purpose, we need the notion of auxiliary terms. For \( \Delta \subseteq G \)

function Aux(\( \Delta \))

repeat
   \( \Delta' := \Delta \);
   \( \Delta := \text{AddTerms}(\Delta') \)
until \( \Delta = \Delta' \);
return \( \Delta \)

function AddTerms(\( \Delta \))

\( \Delta' := \Delta \);

for each \( \alpha \rightarrow \beta \in R^{(i)} \)
do
   \( \alpha' := \text{linearize}(\alpha) \);

   for each \( s \in \Delta, p \in \mathcal{O}_{\mathcal{D} \setminus R^{(i)}_C} (s), \)
   
   \( \sigma : V(\alpha') \rightarrow \text{Bud}(\{ s|_p \}, R^{(i)}_C) \) such that \( \sigma \in \downarrow (=, R^{(i)}_C) \)
do
   
   \( \text{if } s|_p \rightarrow_{R^{(i)}_C} \alpha' \sigma \text{ then } \Delta' := \Delta' \cup \{ s|'_p \} \)

return \( \Delta' \)

**Example 17** In TRS \( R^{(i)}_C \) of Example 2,

\( \text{Aux}(\{ \text{not}(\text{nand}(t, t)) \}) = \text{AddTerms}(\{ \text{not}(\text{nand}(t, t)) \}) = \{ \text{not}(\text{nand}(t, t)), \text{not}(\text{not}(t)) \} \).

**Lemma 18** For any ground term \( s \),

1. For any \( s' \in \text{Aux}(\{ s \}) \), \( \text{Aux}(\{ s' \}) \subseteq \text{Aux}(\{ s \}) \).
2. \( \text{Aux}(\{ s \}) \) is finite and computable.
3. For any \( s' \in \text{Aux}(\{ s \}) \), \( s' \downarrow_{R^{(i)}} s \).
4. If \( s \rightarrow_{R^{(i)}} t \) then there exists \( s' \in \text{Aux}(\{ s \}) \) such that \( s' \rightarrow_{R^{(i)}} t \).

We call \( s' \) in Lemma 18(4) an auxiliary term of \( (s, t) \). This will be used to transform non-right-ground rewrite sequence to right-ground rewrite sequence.

**Example 19** For rewrite sequence \( \text{not}(\text{nand}(t, t)) \rightarrow_{R^{(i)}} \text{not}(\text{nand}(\text{not}(f), \text{not}(t))) \rightarrow \text{not}(\text{not}(\text{not}(f))) \), we can choose \( \text{not}(\text{not}(t)) \in \text{Aux}(\{ \text{not}(\text{nand}(t, t)) \}) \) and \( \text{not}(\text{not}(t)) \rightarrow_{R^{(i)}} \text{not}(\text{not}(f)) \).
3.4 Joinability for Confluent Semi-Constructor TRSs

Lemma 20 For any ground terms $s$ and $t$, $s \downarrow_{R(0)} t$ iff there exists $s' \in \text{Aux(\{s\})}, t' \in \text{Aux(\{t\})}$ such that $s' \downarrow_{R(0)} t'$.

By Lemma 18(2) and decidability of $s' \downarrow_{R(0)} t'$ [10], $s \downarrow_{R(0)} t$ is decidable for ground terms $s$ and $t$. If $s$ or $t$ is non-ground, $s \downarrow_{R(0)} t$ is equivalent to $s\sigma \downarrow_{R(0)} t\sigma$ where $\sigma : V(s) \cup V(t) \rightarrow F'_0$ is a bijection and $F'_0$ is a set of new pairwise distinct constants which do not appear in $R(0)$. Thus, we have the following theorem.

Theorem 21 The joinability for confluent semi-constructor term rewriting systems is decidable.

By confluence, we have the following corollary too.

Corollary 22 The word problem for confluent semi-constructor term rewriting systems is decidable.

4 $R$-Unification

By using Theorem 21, we have the following theorem.

Theorem 23 The unification problem for confluent semi-constructor term rewriting systems is decidable.

5 Conclusion

In this paper, we have shown that the joinability and unification problems for confluent semi-constructor TRSs are decidable. But, reachability remains open. Obviously, the class of semi-constructor TRSs is a subclass of strongly weight-preserving TRSs, for which several sufficient conditions to ensure confluence are given in [3].
