Fourier transforms of invariant functions
on finite reductive Lie algebras

Emmanuel LETELLIER

Abstract: Let $G$ be a connected reductive group defined over $\mathbb{F}_q$ with Lie algebra $\mathcal{G}$. We give two definitions of a Deligne-Lusztig induction for the $\overline{\mathbb{Q}}_{\ell}$-valued functions on $G(\mathbb{F}_q)$ which are invariant under the adjoint action of $G(\mathbb{F}_q)$ on $G(\mathbb{F}_q)$. The first definition is based on the two-variable Green functions defined in group theoretical terms (using $\ell$-adic cohomology) and then transferred to the Lie algebra by means of a $G$-equivariant bijection $G_{uni} \rightarrow O_{uni}$. The second one involves the Lie algebra version of Lusztig's character sheaves theory. We formulate a conjecture about a commutation formula between Deligne-Lusztig induction and Fourier transforms. Using those two definitions of Deligne-Lusztig induction, we establish this conjecture in almost all cases.

The importance of such a conjecture comes from the fact that it reduces [Leto3b] the computation of the trigonometric sums [Spr76] on $G(\mathbb{F}_q)$ to the computation of some fourth roots of unity coming from Fourier transforms [Lus87] and the values of the generalized Green functions defined by Lusztig.

Introduction

Let $G$ be a connected reductive group over an algebraic closure $\mathbb{F}$ of the finite field $\mathbb{F}_q$ with $q$ elements and let $p$ be the characteristic of $\mathbb{F}$. Assume that $G$ is defined over $\mathbb{F}_q$ with associated Frobenius endomorphism $F$. Then the Lie algebra $\mathcal{G}$ of $G$ and the adjoint action of $G$ on $\mathcal{G}$ are also defined over $\mathbb{F}_q$. We still denote by $F$ the corresponding Frobenius endomorphism on $\mathcal{G}$. We then denote by $G^{\mathbb{F}}$ (resp. $\mathcal{G}^{\mathbb{F}}$) the set of the elements of $G$ (resp. $\mathcal{G}$) which are fixed by $F$. Let $\ell$ be a prime $\neq p$ and let $\overline{\mathbb{Q}}_{\ell}$ be an algebraic closure of the field $\mathbb{Q}_{\ell}$ of $\ell$-adic numbers. We denote by $\mathcal{C}(G^{\mathbb{F}})$ the $\overline{\mathbb{Q}}_{\ell}$-vector space of $\overline{\mathbb{Q}}_{\ell}$-valued functions on $G^{\mathbb{F}}$ which are invariant under the adjoint of $G^{\mathbb{F}}$ on $G^{\mathbb{F}}$. Assume that $p$ and $q$ are large enough so that there exists a $G$-invariant bilinear form $\mu : \mathcal{G} \times G \rightarrow \mathbb{F}$ defined over $\mathbb{F}_q$, and let $\Psi : \mathbb{F}_q \rightarrow \overline{\mathbb{Q}}_{\ell}$ be a non-trivial additive character of $\mathbb{F}_q$. Then the Fourier transform $\mathcal{F} : \mathcal{C}(G^{\mathbb{F}}) \rightarrow \mathcal{C}(G^{\mathbb{F}})$ with respect to the pair $(\mu, \Psi)$ is defined by the following formula

$$ \mathcal{F}^{\mathcal{G}}(f)(x) = |G^{\mathbb{F}}|^{-\frac{1}{2}} \sum_{y \in G^{\mathbb{F}}} \Psi(\mu(x, y)) f(y) $$

where $f \in \mathcal{C}(G^{\mathbb{F}})$ and $x \in G^{\mathbb{F}}$. The functions of the form $\mathcal{F}^{\mathcal{G}}(\xi_0)$, where $\xi_0$ is the characteristic function of a $G^{\mathbb{F}}$-orbit $\mathcal{O}$ of $G^{\mathbb{F}}$, form a basis of $\mathcal{C}(G^{\mathbb{F}})$ and are called trigonometric sums. They were first introduced by Springer [Spr71] [Spr76] in connection with the $\overline{\mathbb{Q}}_{\ell}$-character theory of finite groups of Lie type: it was shown by Kazhdan [Kaz77], using the results of [Spr76], that the values of the Green functions of finite groups of Lie type can be expressed (via the exponential map) in terms of the values of trigonometric sums of the form $\mathcal{F}(\xi_0)$ with $\mathcal{O}$ semi-simple regular.
The first motivation of this work is to study trigonometric sums using the techniques developed principally by Lusztig to study the irreducible \( \overline{Q}_F \)-characters of finite groups of Lie type. In particular this suggests the existence of a "twisted" induction for Lie algebras which would fit to the study of trigonometric sums, that is, which would commute with Fourier transforms. Gus Lehrer has proved [Leh96] that Harish-Chandra induction commutes with Fourier transforms, suggesting thus to define the required twisted induction as a generalization of Harish-Chandra induction. A natural reflex would be to adapt the definition of Deligne-Lusztig induction [DL76] to the Lie algebra case, however the definition is not directly adaptable since there is no "action" of the Lie algebra on the cohomology of Deligne-Lusztig varieties. The definition of Deligne-Lusztig we give here uses the "character formula" where the "two-variable Green functions" are defined in group theoretical terms and then transferred to the Lie algebra via a \( G \)-equivariant homeomorphism from the nilpotent variety \( \mathcal{N} \) onto the unipotent variety \( G_{\text{uni}} \). Our definition of Deligne-Lusztig induction is thus available if such a map \( \mathcal{N} \rightarrow G_{\text{uni}} \) is well-defined which is the case if \( p \) is good for \( G \) [Spr69]. Let \( L \) be the Lie algebra of an \( F \)-stable Levi subgroup \( L \) of \( G \) and let \( \mathcal{R}_L^G : \mathcal{C}(L^F) \rightarrow \mathcal{C}(G^F) \) denote the Deligne-Lusztig induction; the author conjectured the following commutation formula

\[
(*) \quad \mathcal{R}_L^G \circ \mathcal{F}^G = \eta_G \eta_L \mathcal{F}^G \circ \mathcal{R}_L^G
\]

where \( \mathcal{F}^G \) is the Fourier transforms with respect to \( (\mu|_{D \times L}, \Psi) \) and \( \mathcal{F}_G = (-1)^{\text{rank}(G)} \). If \( L \) is a Levi subgroup of an \( F \)-stable parabolic subgroup of \( G \), then the formula (*) is a result of G. Lehrer [Leh96] since in that case \( \mathcal{R}_L^G \) is the Harish-Chandra induction. Using the Lie algebra version of Lusztig character sheaves theory, we have another definition of Deligne-Lusztig induction which does not involve any map \( \mathcal{N} \rightarrow G_{\text{uni}} \) (proving thus the independence of our definition of Deligne-Lusztig induction from the choice of such a map). Using these two definitions of Deligne-Lusztig induction, the above commutation formula is proved in many cases (including the cases where the root system \( G \) does not have components of type \( D_n \) or where \( L \) is a maximal torus). Now using the commutation formula (*), we can reduce the computation of trigonometric sums on \( G^F \) to the computation of some constants coming from Fourier transforms [Lus87] (called Lusztig's constants) and the computation of the generalized Green functions defined by Lusztig [Lus85] (a preliminary version of these results is available from [Let03b]). The Lusztig constants have been computed by Digne-Lehrer-Michel [DLM97] in the case of groups of type \( A_n \), by Waldspurger [Wal01] in the case of groups of type \( C_n \) and in the case of the special orthogonal groups \( SO_n(F) \), and by Kawanaka [Kaw86] in the exceptional cases \( E_8, F_4 \) and \( G_2 \). Moreover Lusztig has given an algorithm which reduces the computation of the values of generalized Green functions to the computation of some roots of unity whose values are known in many cases (Shoji has recently computed these roots of unity in type \( A_n \)).

This paper is essentially a résumé of [Let03b]. In section 1, we study some properties of algebraic groups and their Lie algebras related to the characteristic \( p \) in order to have an explicit range of values of \( p \) for which the Lie algebra version of Lusztig character sheaves theory applies. In sections 2 and 3, we give the two definitions of Deligne-Lusztig induction mentioned above. In sections 4, we explain how the conjecture (*) reduces to verify a property on the Lusztig constants [Lus87] attached to the "cuspidal pairs" of the simple groups of classical type. In section 5, we give a formula for the Lusztig constants attached to the "cuspidal pairs" of simple groups, generalizing a preliminary formula given in [DLM97] for the "regular" case. However our formula is not explicit enough to verify the required property on Lusztig's constants. So we have to use the results of [DLM97], [Wal01]; we then see that only the case of the spin groups of type \( D_n \) remains. Finally we state our results concerning (*).
Notation 0.1. Let $H$ be a linear algebraic group over $F$. If $x \in H$, we denote by $x_s$ the semisimple part of $x$ and by $x_u$ the unipotent part of $x$. We denote by $H^0$ the neutral component of $H$ and by $Z_H$ the center of $H$. If $x \in H$, the centralizer of $x$ in $H$ is denoted by $C_H(x)$; it will be more convenient to denote the neutral component of $C_H(x)$ by $C_H^0(x)$ rather than by $C_H(x)^0$. Let $\mathcal{H}$ be the Lie algebra of $H$, for $x \in \mathcal{H}$, we denote by $x_s$ the semisimple part of $x$ and by $x_u$ the nilpotent part of $x$. We denote by $[,]$ the Lie product on $\mathcal{H}$ and by $z(\mathcal{H}) := \{x \in \mathcal{H} | [y, x] = 0\}$. We have a inclusion $\text{Lie}(Z_H) \subseteq z(\mathcal{H})$. If $f : H \to X$ is a morphism of algebraic varieties over $F$, we denote by $df$ its differential at 1. The adjoint action of $H \to \text{GL}(\mathcal{H})$ is denoted by $\text{Ad} = \text{Ad}_H$ and we put $ad = \text{ad}_H = d(\text{Ad}_H)$; recall that $\text{ad}(x)(y) = [x, y]$. Let $K$ be a subgroup of $H$, by “$H$-orbit of $\mathcal{H}$”, we shall mean “$\text{Ad}(K)$-orbit of $\mathcal{H}$” and if $x \in \mathcal{H}$, we denote by $O^K_x$ the $K$-orbit of $x$. If $x \in \mathcal{H}$, then we denote by $C_H^0(x)$ the centralizer of $x$ in $H$ i.e. $C_H^0(x) = \{h \in H | \text{Ad}(h)x = x\}$ and by $C_H(x) := \{y \in \mathcal{H} | [x, y] = 0\}$. If $x \in \mathcal{H}$ is semi-simple, we have $\text{Lie}(C_H^0(x)) = C_H(x)$ [Bor, 9.1].

Notation 0.2. Let now $G$ be a connected reductive algebraic group over $F$ with Lie algebra $\mathcal{G}$. We assume that $G$ is defined over $F_q$, with $q$ a power of a prime $p$, and we denote by $P$ the corresponding Frobenius endomorphisms on $G$ and on $\mathcal{G}$. If $P$ is a parabolic subgroup of $G$, we will denote by $U_P$ the unipotent radical of $P$ and by $L_P$ the Lie algebra of $U_P$. If $P = LU_P$, with corresponding Lie algebra decomposition $P = L \oplus U_P$, is a Levi decomposition in $G$, we denote by $\pi_P : P \to L$ and $\pi_P : P \to L$ the corresponding canonical projections. The letter $T$ will denote a maximal torus of $G$ and its Lie algebra will be denoted by $\mathcal{T}$. The dimension of $T$ is called the rank of $G$ and is denoted by $rk(G)$. As usual, we denote by $X(T)$ the group of algebraic group homomorphisms $T \to F^\times$ and by $\Phi = \Phi(T) \subset X(T)$ the root system of $G$ with respect to $T$. The $Z$-sublattice of $X(T)$ generated by $\Phi$ is denoted by $Q(\Phi)$ and the $Z$-lattice of weights is denoted by $P(\Phi)$. The group $G$ is said to be semi-simple if $Q(\Phi)$ is of finite index in $X(T)$ (which condition is equivalent to $Q(\Phi) \subseteq X(T) \subseteq P(\Phi)$ ) and $G$ is said to be simple if it is semi-simple and if $\Phi$ is irreducible. The group $G$ is then said to be adjoint if $X(T) = Q(\Phi)$ and simply connected if $X(T) = P(\Phi)$. Recall that an $F$-stable torus $H \subset G$ of rank $n$ is said to be split if there exists an isomorphism $H \simeq (F^\times)^n$ defined over $F_q$. The $F_q$ rank of an $F$-stable maximal torus of $G$ is defined to be the rank of its maximum split torus. An $F$-stable maximal torus of $G$ is said to be $G$-split if it is maximally split in $G$. The $F_q$-rank of $G$ is the $F_q$-rank of its $G$-split maximal torus. An $F$-stable Levi subgroup $L$ of $G$ is $G$-split if it has a $G$-split maximal torus; this is equivalent of saying that $L$ is the Levi subgroup of an $F$-stable parabolic subgroup of $G$.

1 About reductive groups and their Lie algebras

The following results are well-known, however their proof are not always easily available in the literature. For complete proof of the following results which are not refered, see [Let03b]. The following result give a necessary and sufficient condition on $p$ for $\text{Lie}(Z_G) \subseteq z(G)$ to be an equality:

Proposition 1.1. The following assertions are equivalent:

(i) the prime $p$ does not divide $|\langle X(T)/Q(\Phi) \rangle_{tor}|$.
(ii) $\text{Lie}(Z_G) = z(G)$.

This result has the following easy consequence:
Corollary 1.2. Assume $G$ semi-simple and let $G = G_1 \cdots G_r$ be the decomposition of $G$ as a product of simple algebraic groups $G_i$. If $p$ does not divide $|X(T)/Q(T)|$, then $G = \bigoplus_i \text{Lie}(G_i)$.

By a $G$-invariant bilinear form $\mu$ on $G$, we shall mean a symmetric bilinear form $\mu : G \times G \to F$ such that for any $g \in G$, $x, y \in G$, we have $\mu(Ad(g)x, Ad(g)y) = \mu(x, y)$. A well-known example of such a form is the Killing form defined on $G \times G$ by $(x, y) \mapsto \text{Trace}(\text{ad}(x) \circ \text{ad}(y))$. As far as I know, no necessary and sufficient condition on $p$ for the existence of non-degenerate $G$-invariant bilinear forms on $G$ has been given in the literature. Here we give such a condition on $p$ when $G$ is simple of type $A_n$ or when $G$ is simply connected of type either $B_n$, $C_n$ or $D_n$.

Recall that a prime is said to be good for $G$ if it does not divide the coefficient of the highest root of $\Phi$. If a good prime for $G$ does not divide $|P(\Phi)/Q(\Phi)|$, it is said to be very good for $G$. Recall that if $\Phi$ does not have irreducible components of type $A_n$, then the very good primes for $G$ are the good ones.

From [SS70, I, 5.3], it is known that if $G$ is simple and if $p$ is very good for $G$, or $G = GL_n(F)$, then there exists a non-degenerate $G$-invariant bilinear form on $G$. Using a Lie algebra isomorphism $G \simeq \text{Lie}(Z_G) \oplus (G/\text{Lie}(Z_G))$, it follows from 1.2 applied to $G/Z_G$, that the above result can be extended to the case of reductive groups, that is if $p$ is very good for $G$ reductive, there exists a non-degenerate $G$-invariant bilinear form on $G$. We have the following proposition:

Proposition 1.3. Assume $G$ simple and let $\mu$ be the proposition "there exists a non-degenerate $G$-invariant bilinear form on $G$".

(i) If $G$ is of type $A_n$, then $\mu$ holds if and only if $p$ is very good for $G$ or $p$ divides both $|X(T)/Q(\Phi)|$ and $|P(\Phi)/X(T)|$.

(ii) If $G$ is simply connected of type either $B_n$, $C_n$ or $D_n$, then $\mu$ holds if and only if $p$ is good for $G$.

Note that the restriction to $z(G)$ of a non-degenerate $G$-invariant bilinear form on $G$ might be degenerate, this happens for instance if we take the form $(x, y) \mapsto \text{Trace}(xy)$ on $G$ with $G = GL_n(F)$ and $p | n$. However if $p$ is very good for $G$, this situation does not happen, more precisely we have:

Proposition 1.4. Assume that $p$ is very good for $G$ and let $\mu$ be a non-degenerate $G$-invariant bilinear form on $z(G) \oplus (G/z(G)) \simeq G$. Then the subspace $z(G)$ is the orthogonal complement of $G/z(G)$ in $G$ with respect to $\mu$. In particular, the restrictions of $\mu$ to $z(G)$ and to $G/z(G)$ remain non-degenerate.

Lemma 1.5. [Leh86, proof of 4.3] Let $\mu$ be a non-degenerate $G$-invariant bilinear form on $G$. The restriction of $\mu$ to any Levi subalgebra is still non-degenerate.

Now let $L$ be a Levi subgroup of $G$ with Lie algebra $L$. Note that if $x \in G$ satisfies $C^G_L(x) = L$, then $x \in z(L)$. Define $z(L)_{\text{reg}} := \{ x \in G | C^G_{L}(x) = L \}$.

Proposition 1.6. (i) If $p$ is good for $G$, then for any semi-simple element $x \in G$, the group $C^G_L(x)$ is a Levi subgroup of $G$.

(ii) If $p$ is good for $G$ and if $p$ does not divide $|(X(T)/Q(\Phi))_{\text{reg}}|$, then for any Levi subgroup $L$ of $G$, the set $z(L)_{\text{reg}}$ is not empty.
The assertion 1.6(i) comes from the fact that for $x \in \text{Lie}(T)$, the set $\{ \alpha \in \Phi | d\alpha(x) = 0 \}$ is a $\mathbb{Q}$-closed root subsystem of $\Phi$ [Slo80, 3.14]. The assertion 1.6(ii) is proved using 1.6(i) and 1.1.

2 Twisted induction: a first definition

For a full detailed version of this section, see [Let03a].

Assumption 2.1. In this section, we assume that $p$ is good for $G$ so that there exists a $G$-equivariant homeomorphism $\phi : G_{\text{uni}} \rightarrow G_{\text{uni}}$ defined over $\mathbb{F}_q$, where $G$ acts by the adjoint action on the nilpotent variety $G_{\text{uni}}$ and by conjugation on the unipotent variety $G_{\text{uni}}$.

Lemma 2.2. [Bon08, Lemma 3.2] For any Levi decomposition $P = LU_P$ in $G$ with corresponding Lie algebra decomposition $P = \mathcal{L} \oplus U_P$, we have:

(i) $\overline{\phi}(L_{\text{uni}}) = L_{\text{uni}}$.

(ii) For any $x \in L_{\text{uni}}$, $\overline{\phi}(x + U_P) = \overline{\phi}(x)U_P$.

For a variety $X$ over $\mathbb{F}$, we denote by $H^i_c(X, \overline{\mathbb{Q}})$ the $i$-th group of $\ell$-adic cohomology with compact support as in [Del77].

Let $L$ be an $F$-stable Levi subgroup of $G$, let $P = LU_P$ be a Levi decomposition of a (possibly non $F$-stable) parabolic subgroup $P$ of $G$ and let $P = \mathcal{L} \oplus U_P$ be the corresponding Lie algebra decomposition. We denote by $L_G$ the Lang map $G \rightarrow G, x \mapsto x^{-1}F(x)$. The variety $\mathcal{L}_{G}^{-1}(U_P)$ is endowed with an action of $G^F$ on the left and with an action of $L^F$ on the right. These actions induce actions on the cohomology and so make $H^*_c(\mathcal{L}_{G}^{-1}(U_P), \overline{\mathbb{Q}})$ into a $G^F$-module-$L^F$. The virtual $\overline{\mathbb{Q}}$-vector space $H^*_c(\mathcal{L}_{G}^{-1}(U_P)) := \sum_r (-1)^r H^r_c(\mathcal{L}_{G}^{-1}(U_P), \overline{\mathbb{Q}})$ is thus a $G^F$-module-$L^F$.

The two-variable Green function $\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}} : G_{\text{uni}} \times L_{\text{uni}} \rightarrow \mathbb{Z}$ is defined by

$$\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(u, v) = |L^F|^{-1} \text{Trace}(\overline{\phi}(u), \overline{\phi}(v)^{-1})| H^*_c(\mathcal{L}_{G}^{-1}(U_P))).$$

We "extend" this function to a function $\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}} : G^F \times L^F \rightarrow \overline{\mathbb{Q}}_\ell$ as follows: for $(x, y) \in G^F \times L^F$, define

$$\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(x, y) = \sum_{h \in G^F/\text{Ad}(h)y = x} |C^G_{\mathcal{L}}(y_{\alpha})| |C^G_{\mathcal{L}}(y_{\alpha})|^{-1} \mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(y_{\alpha}) (\text{Ad}(h^{-1}) x_{\alpha}, y_{\alpha}).$$

Remark 2.3. (i) If $(u, v) \in G_{\text{uni}} \times L_{\text{uni}}$, then $\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(u, v) = |L^F| \mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(u, v)$.

(ii) The function $\mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}$ is the Lie algebra analogue of the function $G^F \times L^F \rightarrow \overline{\mathbb{Q}}_\ell$ given by $(g, l) \mapsto \text{Trace}(\overline{\phi}(l)H^*_c(\mathcal{L}_{G}^{-1}(U_P))))$ as it can be seen from [DM91, 12.3].

Definition 2.4. The Deligne-Lusztig induction $\mathcal{R}_{\mathcal{L} \subset \mathcal{P}}^G : C(L^F) \rightarrow C(G^F)$ is defined by:

$$\mathcal{R}_{\mathcal{L} \subset \mathcal{P}}^G(f)(x) = |L^F|^{-1} \sum_{y \in L^F} \mathcal{Q}^G_{\mathcal{L} \subset \mathcal{P}}(x, y) f(y) \quad \text{for } f \in C(L^F) \text{ and } x \in G^F.$$

Deligne-Lusztig induction satisfies the following elementary properties analogous to the group case:
Proposition 2.5. (i) If $P$ is $F$-stable, then $\mathcal{R}_{\mathcal{L}\subset \mathcal{P}}^{G}(f)(x) = |P^{F}|^{-1} \sum_{g \in G^{P} | \text{Ad}(g) \in P^{F}} f(\pi_{P}(\text{Ad}(g) x))$.

(ii) Deligne-Lusztig induction is transitive, and satisfies the Mackey formula.

(iii) $\mathcal{R}_{\mathcal{L}\subset \mathcal{P}}^{G}$ does not depend on $P$, and commutes with the duality map.

3 Twisted induction: a second definition

Starting from [Lus87] and by adapting Lusztig's ideas to the Lie algebra case, we have a Lie algebra version of Lusztig's character sheaves theory under the condition "$p$ is acceptable" (see below) leading to the definition of a twisted induction which is better adapted to the study of Fourier transforms. This section is a dense résumé of [Let08b, Chapter 3].

In the following assumption, by a cuspidal pair of $G$, we shall mean a cuspidal pair $(S, \mathcal{E})$ of $G$ in the sense of [Lus84, 2.4] such that $S$ contains a unipotent conjugacy class of $G$.

Assumption 3.1. In this section, we assume that $p$ is acceptable for $G$ i.e. that $p$ satisfies the following conditions:

(i) $p$ is good for $G$.
(ii) $p$ does not divide $|\mathbb{Q}(\Phi)|_{\text{tor}}$.
(iii) There exists a non-degenerate $G$-invariant bilinear form $\mu$ on $\mathcal{G}$.
(iv) $p$ is very good for any Levi subgroup of $G$ supporting a cuspidal pair.
(v) There exists a $G$-equivariant isomorphism $\Phi : G_{\text{uni}} \rightarrow G_{\text{uni}}$.

The following result can be easily deduced from the results of section 1 and the classification of the cuspidal data of $G$ [Lus84]:

Lemma 3.2. (i) If $p$ is acceptable for $G$, then it is acceptable for any Levi subgroup of $G$.
(ii) If $p$ is very good for $G$, then it is acceptable for $G$.
(iii) All primes are acceptable for $G = \text{GL}_{n}(\mathbb{F})$.
(iv) If $G$ is simple, the very good primes are the acceptable ones for $G$.

3.1 Admissible complexes (or character sheaves) on $G$

Notation 3.3. Let $X$ be a variety over $\mathbb{F}$. We denote by $\text{Sh}(X)$ the abelian category of $\overline{\mathbb{Q}}_{p}$-sheaves on $X$ and we denote by $\mathbb{Q}_{\text{c}}$, the constant sheaf on $X$. We denote by $\mathcal{D}_{\text{c}}^{b}(X)$ the bounded "derived category" of $\mathbb{Q}_{\text{c}}$-(constructible) sheaves as in [BBD82, 2.2.18]. By a complex on $X$ we shall mean an object of $\mathcal{D}_{\text{c}}^{b}(X)$. For $K \in \mathcal{D}_{\text{c}}^{b}(X)$, the $i$-th cohomology sheaf of $K$ is denoted by $\mathcal{H}^{i}K$. If $f : X \rightarrow Y$ is a morphism of varieties, we have the usual functors $f_{*} : \text{Sh}(X) \rightarrow \text{Sh}(Y)$ (direct image), $f_{!} : \text{Sh}(X) \rightarrow \text{Sh}(Y)$ (inverse image) and the functors $Rf_{*} : \mathcal{D}_{\text{c}}^{b}(X) \rightarrow \mathcal{D}_{\text{c}}^{b}(Y)$, $Rf_{!} : \mathcal{D}_{\text{c}}^{b}(X) \rightarrow \mathcal{D}_{\text{c}}^{b}(Y)$ and $Rf^{*} : \mathcal{D}_{\text{c}}^{b}(Y) \rightarrow \mathcal{D}_{\text{c}}^{b}(X)$ as in [Gro73, Exposé XVII]. The functors $Rf_{*}$, $Rf_{!}$, $Rf^{*}$ commute with the shift operations $[m]$ (if $K \in \mathcal{D}_{\text{c}}^{b}(X)$, the $m$-th shift of $K$ is denoted by $K[m]$; for any integer $i$, we have $\mathcal{H}^{i}(K[m]) = \mathcal{H}^{i+m}K$). If there is no ambiguity we will denote by $f_{*}$, $f_{!}$ and $f^{*}$ the functors $Rf_{*}$, $Rf_{!}$ and $Rf^{*}$.

We denote by $\mathcal{M}(X)$ the full subcategory of $\mathcal{D}_{\text{c}}^{b}(X)$ consisting of perverse sheaves on $X$. Recall
that $\mathcal{M}(X)$ is abelian. Note that if $X$ is smooth of pure dimension, then for any $\xi \in \mathcal{L}(X)$, the complex $\xi(\dim X)$ is a perverse sheaf on $X$. For a locally closed smooth irreducible subvariety $Y$ of $X$ together with a local system $\xi$ on $Y$, we denote by $\text{IC}(\overline{Y}, \xi) \in \mathcal{D}^b_c(\overline{Y})$ the corresponding intersection cohomology complex defined by Goresky-MacPherson and Deligne [BBBD82]. Then the complex $\text{IC}(\overline{Y}, \xi)[\dim Y]$ is a perverse sheaf on $\overline{Y}$; moreover it is simple if $\xi$ is irreducible. Recall that any simple perverse sheaf on $X$ is of the form $j_!(\text{IC}(\overline{Y}, \xi)[\dim Y])$ with $j : \overline{Y} \hookrightarrow X$ for some $(Y, \xi)$ as above with $\xi$ irreducible.

**Notation 3.4.** Let $H$ denote a connected linear algebraic group over $F$ acting algebraically on $X$. Let $\mathbb{S}_H(X)$ (resp. $\mathcal{M}_H(X)$) be the category of $H$-equivariant sheaves (resp. $H$ equivariant perverse sheaves) on $X$. They are respectively full subcategories of $\mathcal{S}_H(X)$ and $\mathcal{M}(X)$. If $\pi : H \times X \rightarrow X$ is the second projection and $\rho : H \times X \rightarrow X$ is the action of $H$ on $X$, then the $H$-equivariant perverse sheaves, resp. the $H$-equivariant perverse sheaves, on $X$ can be identified with $\{\xi \in \mathbb{S}_H(X) | \pi^*\xi \simeq \rho^*\xi\}$, resp. $\{K \in \mathcal{M}(X) | \pi^*K \simeq \rho^*K\}$. We denote by $\mathcal{I}_H(X)$ the full subcategory of $\mathbb{S}_H(X)$ consisting of $H$-equivariant local systems on $X$.

**Notation 3.5.** Assume that $X$ is defined over $\mathbb{F}_q$ with Frobenius endomorphism $F : X \rightarrow X$. A complex (or sheaf) $K$ on $X$ is said to be $F$-stable if $F^*K$ is isomorphic to $K$. An $F$-equivariant complex (resp. sheaf) on $X$ is a pair $(K, \phi)$ with $K \in \mathcal{D}^b_c(X)$ (resp. $K \in \mathcal{S}_H(X)$) and $\phi : F^*K \rightarrow K$ an isomorphism. The morphisms of $F$-equivariant complexes (or sheaves) are the obvious ones. If $(K, \phi)$ is an $F$-equivariant complex on $X$, we define the characteristic function $X_{K, \phi} : X^F \rightarrow \mathbb{Q}^*_F$ of $(K, \phi)$ by $X_{K, \phi}(x) = \sum(-1)^i\text{Trace}(\phi_x, K^i)$ where $\phi_x$ is the automorphism of $\mathcal{H}^i_xK$ induced by $\phi$. If $(\mathcal{E}, \phi)$ is an $F$-equivariant sheaf on $X$, the characteristic function $X_{\mathcal{E}, \phi} : X^F \rightarrow \mathbb{Q}^*_F$ of $(\mathcal{E}, \phi)$ is then defined by $X_{\mathcal{E}, \phi}(x) = \text{Trace}(\phi_x, \mathcal{E}_x)$. If $(K, \phi)$ and $(K', \phi')$ are two isomorphic $F$-equivariant complexes (or sheaves), then their characteristic functions are equal. Let $(K, \phi)$ and $(K', \phi')$ be two $F$-equivariant simple perverse sheaves (or two irreducible local systems) on $X$ such that $K \simeq K'$, then $\phi = c\phi'$ for some $c \in \mathbb{Q}^*_F$. Moreover if $c = 1$, then $(K, \phi) \simeq (K', \phi')$. Now let $H$ and $\rho$ be as in 3.4. If $H$ and $\rho$ are both defined over $\mathbb{F}_q$, then the characteristic function of any $F$-equivariant $H$-equivariant perverse sheaf (or sheaf) on $X$ is an $H^F$-invariant function on $X^F$.

**Notation 3.6.** If $\Sigma$ is a $G$-stable (for the adjoint action) locally closed, smooth, irreducible subset of $G$ and if $\mathcal{E}$ is a $G$-equivariant local system on $\Sigma$, then we will denote by $K(\Sigma, \mathcal{E})$ the $G$-equivariant perverse sheaf $j_!(\text{IC}(\Sigma, \mathcal{E})[\dim \Sigma])$ where $j : \Sigma \hookrightarrow G$.

3.7. We define the parabolic induction of equivariant perverse sheaves as in [Lus87]: let $P$ be a parabolic subgroup of $G$ and $LU_P$ be a Levi decomposition of $P$. Let $\mathcal{P} = L \oplus U_P$ be the corresponding Lie algebra decomposition. Define $V_1 = \{(X, h) \in G \times \text{Ad}(h^{-1})X | X \in \mathcal{P}\}$ and $V_2 = \{(X, hP) \in G \times (G/P) | \text{Ad}(h^{-1})X \in \mathcal{P}\}$. Then we have the following diagram

$$L \rightarrow V_1 \rightarrow V_2 \rightarrow G$$

where $\pi^*(X, hP) = X$, $\pi'(X, hP) = (X, hP)$, $\pi(X, h) = \pi_\rho(\text{Ad}(h^{-1})X)$. Let $K$ be an object in $\mathcal{M}_L(L)$. The morphism $\pi$ is smooth with connected fibers of dimension $m = \dim G + \dim U_P$ and is $P$-equivariant with respect to the action of $P$ on $V_1$ and on $L$ given respectively by $x.(X, h) = (X, hx^{-1})$ and $x.X = \text{Ad}(xP)(X)$. Hence $\pi^*K[m]$ is a $P$-equivariant perverse sheaf on $V_1$ and since $\pi'$ is a locally trivial principal $P$-bundle there exists a unique perverse sheaf $\tilde{K}$ on $V_2$ such that $\pi^*K[m] = \pi'^*\tilde{K}[\dim P]$. Now we define the induced complex $\text{ind}_{L\rightarrow P}^G K$ of $K$ by $\text{ind}_{L\rightarrow P}^G K = (\pi'^*\tilde{K})_\rho \in \mathcal{D}^b_c(G)$. This process defines a functor $\text{ind}_{L\rightarrow P}^G$ from the category $\mathcal{M}_L(L)$ of $L$-equivariant
perverse sheaves on $L$ to $\mathcal{D}_c^b(G)$. If $K \in \mathcal{M}_L(L)$ is such that $\text{ind}^G_{\mathcal{L}Cp} \in \mathcal{M}(G)$ then $\text{ind}^G_{\mathcal{L}Cp} \in \mathcal{M}(G)$ is automatically a $G$-equivariant perverse sheaf on $G$; indeed the morphisms $\pi, \pi'$ and $\pi''$ are all $G$-equivariant if we let $G$ acts on $V_1$ and $V_2$ by $\text{Ad}$ on the first coordinate and by left translation on the second coordinate, and on $L$ trivially. Note that if $P, L$ and $K$ are all $F$-stable and if $\phi : F^*K \to K$ is an isomorphism, then $\phi$ induces a canonical isomorphism $\psi : F^*(\text{ind}^G_{\mathcal{L}Cp}K) \xrightarrow{\sim} \text{ind}^G_{\mathcal{L}Cp}K$ such that $\mathcal{R}_L(X_{K,h}) = X_{\text{ind}^G_{\mathcal{L}Cp}K, h}$, where $\mathcal{R}_L^G$ is the Harish-Chandra induction (see 2.5(i)).

3.8. Let $(P, L, \Sigma, \mathcal{E})$ be a tuple where $P$ is a parabolic subgroup of $G$, $L$ is a Levi subgroup of $P$, $\Sigma = \mathcal{Z} + C$ with $C$ a nilpotent orbit of $L$ and $\mathcal{Z}$ a closed irreducible smooth subvariety of $z(L)$, and where $\mathcal{E}$ is an $L$-equivariant irreducible local system on $\Sigma$. Let $P = L \oplus U_P$ be the Lie algebra decomposition corresponding to the decomposition $P = LU_P$. Then the complex $\text{ind}^G_{\mathcal{L}Cp}(K(\Sigma, \mathcal{E}))$ is a $G$-equivariant perverse sheaf on $G$. If moreover the local system $\mathcal{E}$ is of the form $\zeta \otimes \xi$ with $\xi \in \mathcal{L}_{\Sigma}(C)$ and $\zeta \in \mathcal{L}_{\Sigma}(Z)$ such that $\zeta(\dim Z)$ is of geometrical origin in the sense of [BBD82, 6.2.4], then the perverse sheaf $\text{ind}^G_{\mathcal{L}Cp}(K(\Sigma, \mathcal{E}))$ is semi-simple.

3.9. Let $(P, L, \Sigma, \mathcal{E})$ be as in 3.8 and assume moreover that $\Sigma_{\text{reg}} := \Sigma \cap (\Sigma-L) \neq \emptyset$. In this situation, we can regard the perverse sheaf $\text{ind}^G_{\mathcal{L}Cp}(K(\Sigma, \mathcal{E}))$ as an intersection cohomology complex on $G$ as follows. Let $\Sigma_{\text{reg}} := \Sigma_{\text{reg}} + C$ and put $Y = \bigcup_{g \in G} \text{Ad}(g)(\Sigma_{\text{reg}})$. The subset $Y$ is then locally closed in $G$, irreducible and smooth of dimension $\dim G - \dim L + \dim \Sigma$. We now construct following [Lus84] a $G$-equivariant semi-simple local system on $Y$: we have a diagram $\Sigma : Y_1 \rightarrow Y_2 \rightarrow Y$ where $Y_1 := (\Sigma, g) \in G \times \text{Ad}(g^{-1})X \in \Sigma_{\text{reg}}$, $Y_2 := (\Sigma, gL) \in G \times (G/L) \text{Ad}(g^{-1})X \in \Sigma_{\text{reg}}$ and $\alpha(X, g) = \text{Ad}(g^{-1})X, \alpha'(X, g) = (X, gL), \alpha''(X, g) = X$. Denote by $\xi_1$ the irreducible $L$-equivariant local system $\xi_1^*(\mathcal{E})$ on $Y_1$ (with respect to the action of $L$ on $Y_1$ given by $\pi(X, g) = (X, g^{-1})$). The $L$-equivariance of $\xi_1$ implies the existence of a unique irreducible local system $\xi_2$ on $Y_2$ such that $(\alpha')^*\xi_2 = \xi_1$. Since $\alpha''$ is a Galois covering with Galois group $W_\mathcal{G}(\Sigma)$, the stabilizer of $\Sigma$ in $W_\mathcal{G}(\Sigma) / L$, the sheaf $L^*(\alpha'')_\xi \xi_2$ is a semi-simple local system on $Y$. Now $G$ acts on $Y$ by $\text{Ad}$ on $Y_1$ and $Y_2$ by $\text{Ad}$ on the first coordinate and by left translation on the second coordinate, and on $\Sigma$ trivially; the morphisms $\alpha, \alpha'$ and $\alpha''$ are then $G$-equivariant from which we deduce that $(\alpha'')^*\xi_2$ is $G$-equivariant. The complex $\text{ind}^G_{\mathcal{L}Cp}(\mathcal{E}) := K(Y, (\alpha''\xi_2))$ is thus a $G$-equivariant semi-simple perverse sheaf on $G$ and each direct summand is $G$-equivariant. Now as in the situation of [Lus84, 4.5], we show that there is a canonical isomorphism

$$\text{ind}^G_{\mathcal{L}Cp}(K(\Sigma, \mathcal{E})) \xrightarrow{\sim} \text{ind}^G_{\mathcal{L}Cp}(\mathcal{E}).$$

**Notation 3.10.** Consider the non-trivial additive character $\Psi : \mathbb{F}_q^* \rightarrow \overline{\mathbb{Q}}_\ell^*$ fixed in the introduction. We denote by $A^1$ the affine line over $\mathbb{F}_q$. Let $h : A^1 \rightarrow A^1$ be the Artin-Schreier covering defined by $h(t) = t^q - t$. Since $h$ is a Galois covering of $A^1$ with Galois group $\mathbb{F}_q$, the sheaf $h_\mathcal{G}$ is a semi-simple local system on $A^1$ on which $\mathbb{F}_q$ acts; we denote by $L_\mathcal{G}$ the subsheaf of $h_\mathcal{G}$ on which $\mathbb{F}_q$ acts as $\Psi^{-1}$. There exists an isomorphism $\phi_{L_\mathcal{G}} : F^*L_\mathcal{G} \xrightarrow{\sim} L_\mathcal{G}$ such that for any integer $i \geq 1$, we have $X_\mathcal{L}_\mathcal{G}, \phi_{L_\mathcal{G}}^{\otimes i} = \Psi \circ T_{\mathcal{L}^i} / F_q : \mathbb{F}_q^* \rightarrow \overline{\mathbb{Q}}_\ell^*$, see [Kat80, 3.5.4].

3.11. We are now in position to define the admissible complexes (or character sheaves) on $G$ [Lus87]. Let $C$ be a nilpotent orbit on $G$ and $\zeta$ an irreducible $G$-equivariant local system on $C$. One says that the pair $(C, \zeta)$ is cuspidal if for any proper Levi decomposition $P = LU_P$ in $G$, we have $(\tau_P)_!(K(C, \zeta)|_{P}) = 0$. By a cuspidal orbital complex, we shall mean a complex of the form $K(C, \mathcal{E})$ with $\mathcal{O} = \sigma + C, \mathcal{E} = \mathcal{L}_\mathcal{G} \otimes \zeta$ where $(C, \zeta)$ is cuspidal and $\sigma \in z(\mathcal{G})$. By a cuspidal admissible complex, we shall mean a complex of the form $K(\Sigma, \mathcal{E})$ whith $\Sigma = z(\mathcal{G}) + C$. 
3.12. We have the following fundamental result: let \((L, \Sigma, \mathcal{E})\) and \((L', \Sigma', \mathcal{E}')\) be two cuspidal data of \(G\). Then the complexes \(\text{ind}^G_E(\mathcal{E})\) and \(\text{ind}^G_{E'}(\mathcal{E}')\) have a common direct summand if and only if \((L, \Sigma, \mathcal{E})\) and \((L', \Sigma', \mathcal{E}')\) are \(G\)-conjugate (i.e. there exists \(g \in G\) such that \(L' = gLg^{-1}\), \(\Sigma' = \text{Ad}(g)\Sigma\) and \(\text{Ad}(g)*\mathcal{E}'\) is isomorphic to \(\mathcal{E}\)), in which case we have \(\text{ind}^G_E(\mathcal{E}) \simeq \text{ind}^G_{E'}(\mathcal{E}')\).

3.2 Endomorphism algebra of \(\text{ind}^G_E(\mathcal{E})\)

Let \((L, \Sigma, \mathcal{E})\) be a cuspidal datum of \(G\). Let \(N_G(\mathcal{E}) := \{n \in N_G(L) | \text{Ad}(n)\Sigma = \Sigma, \text{Ad}(n)*\mathcal{E} \simeq \mathcal{E}\}\) and let \(W_G(\mathcal{E})\) be the finite group \(N_G(\mathcal{E})/L\). We use the notation of 3.9.

Following [Lus84] and [Lus85, 10.2], we are going to describe the endomorphism algebra \(A := \text{End}(\text{ind}^G_E(\mathcal{E}))\) in terms of \(W_G(\mathcal{E})\). Let \(w \in W_G(\mathcal{E})\) and let \(\delta_w : Y_2 \rightarrow Y_1\) be the isomorphism defined by \(\delta_w(X, gL) = (X, gw^{-1}L)\) where \(w\) denotes a representative of \(w\) in \(N_G(\mathcal{E})\); the map \(\delta_w\) does not depend on the choice of the representative \(w\) of \(w\). We have the following cartesian diagram:

\[
\begin{array}{cccccc}
\Sigma & \rightarrow & Y_1 & \rightarrow & Y_2 & \rightarrow & Y \\
\downarrow \text{Ad}(w) & & \downarrow \delta_w & & \downarrow \delta_w' & & \downarrow \delta_w'' \\
\Sigma & \rightarrow & Y_1 & \rightarrow & Y_2 & \rightarrow & Y
\end{array}
\]

where \(f_w(X, g) = (X, gw^{-1})\). From the above diagram we see that any isomorphism \(\text{Ad}(\omega)*\mathcal{E} \simeq \mathcal{E}\) induces a canonical isomorphism \(\delta_w\xi_2 \simeq \xi_2\); conversely since \(\alpha : Y_1 \rightarrow \Sigma_{\text{reg}}\) is a trivial principal \(G\)-bundle if \(G\) acts on \(Y_1\) by left translation on both coordinates and on \(\Sigma_{\text{reg}}\) trivially, the functor \(\alpha^* : \text{Sh}(\Sigma_{\text{reg}}) \rightarrow \text{Sh}_G(Y_1)\) is an equivalence of categories and so any isomorphism \(\delta_w\xi_2 \simeq \xi_2\) defines a unique isomorphism \(\text{Ad}(\uparrow)^*\mathcal{E} \simeq \mathcal{E}\). Using \(\alpha'\) and \(\alpha''\) we identify the one dimensional \(\mathbb{Q}_\ell\)-vector space \(A_w\) of all homomorphisms \(\delta_w'\xi_2 \rightarrow \xi_2\) with a subspace of \(A\). From the previous discussion, we have a natural injective \(\mathbb{Q}_\ell\)-linear map \(\text{Hom}(\text{Ad}(\uparrow)^*\mathcal{E}, \mathcal{E}) \rightarrow A\).

For each \(w \in W_G(\mathcal{E})\), we choose a non-zero element \(\theta_w\) of \(A_w\). Note that for \(w, w' \in W_G(\mathcal{E})\), we have \(\delta_w \circ \delta_{w'} = \delta_{ww'}\). Hence for any \(w, w' \in W_G(\mathcal{E})\), we have \(\theta_w \circ \delta_{w'}(\theta_w) \in A_{ww'}\). We thus have a well-defined product on \(\bigoplus_{w \in W_G(\mathcal{E})} A_w\) given by \(\theta_w \theta_{w'} := \theta_w \circ \delta_{w'}^*(\theta_{w'})\). This makes \(\bigoplus_{w \in W_G(\mathcal{E})} A_w\) into a \(\mathbb{Q}_\ell\)-algebra. Then as in [Lus84, Proposition 3.5], we show that \(\bigoplus_{w \in W_G(\mathcal{E})} A_w \simeq A\) as \(\mathbb{Q}_\ell\)-algebras.

3.3 F-stable admissible complexes

13. Let \((L, \Sigma, \mathcal{E})\) be an \(F\)-stable cuspidal datum of \(G\) i.e. \(F(L) = L\), \(F(\Sigma) = \Sigma\) and \(F^*\mathcal{E} \simeq \mathcal{E}\), and let \(\phi : F^*\mathcal{E} \rightarrow \mathcal{E}\) be an isomorphism. For any \(w \in W_G(\mathcal{E})\), we choose arbitrarily a non-zero element \(\theta_w \in A_w \subset A\), see previous subsection. We fix an element \(w\) of \(W_G(\mathcal{E})\) together with a representative \(w\) of \(w\) in \(N_G(\mathcal{E})\). By the Lang-Steinberg theorem there is an element \(z \in G\) such that \(z^{-1}F(z) = w^{-1}\). Let \(L_w := zLz^{-1}\) and let \(L_w\) be its Lie algebra. Then \(L_w\) and
\[ \Sigma_w := \text{Ad}(z)\Sigma \] are both \( F \)-stable. Let \( \mathcal{E}_w \) be the local system \( \text{Ad}(z^{-1})^* \mathcal{E} \). We now define an isomorphism \( \phi_w : F^* \mathcal{E}_w \cong \mathcal{E}_w \) in terms of \( \phi \). The automorphism \( \theta_w \) defines an isomorphism \( \mathcal{E} \cong \text{Ad}(w)^* \mathcal{E} \). For an isomorphism \( \text{Ad}(z^{-1})^* \mathcal{E} \cong F^* \text{Ad}(z^{-1}) \circ F^* \mathcal{E} \), we have \( \text{Ad}(w) \circ \text{Ad}(z^{-1}) \circ F = F \circ \text{Ad}(w) \circ \text{Ad}(z^{-1}) \), the isomorphism \( \phi \) gives rise to an isomorphism \( h : F^* \text{Ad}(z^{-1})^* \mathcal{E} \cong \text{Ad}(w)^* \mathcal{E} \). Then the isomorphism \( \phi_w : F^* \mathcal{E}_w \cong \mathcal{E}_w \) is \( \text{Ad}(z^{-1}) \circ \phi \circ h \).

We denote by \( \phi^Q : F^*(\text{ind}_\mathcal{H}^A(\mathcal{E})) \cong \text{ind}_\mathcal{H}^A(\mathcal{E}) \) the natural isomorphism induced by \( \phi \) and \( \phi^R : F^*(\text{ind}_\mathcal{H}^A(\mathcal{E}_w)) \cong \text{ind}_\mathcal{H}^A(\mathcal{E}_w) \) the natural isomorphism induced by \( \phi_w \). As in \([\text{Lus85}, \text{10.6}]\), there is a natural isomorphism \( j : \text{ind}_\mathcal{H}^A(\mathcal{E}_w) \cong \text{ind}_\mathcal{H}^A(\mathcal{E}) \) such that the following diagram commutes.

\[
\begin{array}{ccc}
F^*(\text{ind}_\mathcal{H}^A(\mathcal{E}_w)) & \xrightarrow{\phi_w^Q} & F^*(\text{ind}_\mathcal{H}^A(\mathcal{E})) \\
\downarrow j & & \downarrow \text{ind}_\mathcal{H}^A(\mathcal{E}_w) \\
\text{ind}_\mathcal{H}^A(\mathcal{E}_w) & \cong & \text{ind}_\mathcal{H}^A(\mathcal{E})
\end{array}
\]

As a consequence we get that \( X_{\text{ind}_\mathcal{H}^A(\mathcal{E}), \theta_w} = X_{\text{ind}_\mathcal{H}^A(\mathcal{E})} \).

3.14. Let \((L, \Sigma, \mathcal{E})\) be a cuspidal datum of \( \mathcal{G} \), let \( K^G = \text{ind}_\mathcal{H}^A(\mathcal{E}) \) and let \( A = \text{End}(K^G) \). If \( A \) is a simple direct summand of \( K^G \), we denote by \( V_A \) the abelian group \( \text{Hom}(A, K^G) \). Then \( V_A \) is endowed with a structure of \( A \)-module defined by \( \alpha \cdot V_A \mapsto V_A, (a, f) \mapsto a \circ f \); since \( A \) is a simple perverse sheaf, the \( A \)-module \( V_A \) is irreducible. We have a natural isomorphism \( \bigoplus_A (V_A \otimes A) \cong K^G \) where \( A \) runs over the set of simple components of \( K^G \) (up to isomorphism).

For any \( x \in \mathcal{G} \) and any integer \( i \), it gives rise to an isomorphism \( \Sigma_A \otimes (\phi_{A})^i : V_A \otimes \mathcal{H}_{x}^i A \cong V_A \otimes \mathcal{H}_{x}^i A \). Under \( \phi \), an element \( v \circ a \in V_A \otimes \mathcal{H}_{x}^i A \) corresponds to \( v^2(\alpha) \) where \( v^2 : \mathcal{H}_{x}^i A \rightarrow \mathcal{H}_{x}^i K^G \) is the morphism induced by \( v : A \rightarrow K^G \).

Assume now that the datum \((L, \Sigma, \mathcal{E})\) is \( F \)-stable and let \( \phi \) be an isomorphism \( F^* \mathcal{E} \cong \mathcal{E} \). The complex \( K^G \) is thus \( F \)-stable and we denote by \( \phi^Q : F^*K^G \cong K^G \) the isomorphism induced by \( \phi \).

Let \( A \) be an \( F \)-stable simple direct summand of \( K^G \) together with an isomorphism \( \phi_A : F^*A \cong A \).

This defines a linear map \( \sigma_A : V_A \rightarrow V_A \) by \( \phi_A \circ F^*(v) \circ \phi_A^{-1} \). For any \( z \in \mathcal{G}^F \) and any integer \( i \), the isomorphism \( \Sigma_A \otimes (\phi_{A})^i : V_A \otimes \mathcal{H}_{x}^i A \cong V_A \otimes \mathcal{H}_{x}^i A \) corresponds under \( \phi \) to \( (\phi^Q)^i : \mathcal{H}_{x}^i K^G \cong \mathcal{H}_{x}^i A \). On the other hand, if \( B \) is a simple component of \( K^G \) which is not \( F \)-stable, then \( (\phi^Q)^i \) maps \( V_B \otimes \mathcal{H}_{x}^i B \rightarrow \mathcal{H}_{x}^i K^G \) onto a different direct summand. It follows that

\[ X_{K^G, \phi} = \sum_A \text{Tr}(\sigma_A, V_A)X_{A, \theta_A} \]

where \( A \) runs over the set of \( F \)-stable simple components of \( K^G \) (up to isomorphism). If for \( w \in W_G(\mathcal{E}) \), we replace \( \phi \) by \( \theta_w \circ \phi \) with \( \theta_w \) as in 3.13 and we keep \( \phi_A \) unchanged, then the formula 3.15 becomes

\[ X_{K^G, \theta_w, \phi} = \sum_A \text{Tr}(\theta_w \circ \sigma_A, V_A)X_{A, \theta_A} \]

Following \([\text{Lus85}, \text{10.4}]\) we deduce that

\[ X_{A, \phi_A} = [W_G(\mathcal{E})]^{-1} \sum_{w \in W_G(\mathcal{E})} \text{Tr}((\theta_w \circ \sigma_A)^{-1}, V_A)X_{K^G, \theta_w, \phi} \]

for any \( F \)-equivariant complex \((A, \phi_A)\) with \( A \) a simple direct summand of \( K^G \).
We use the notation of 3.13; by 3.13 and 3.17 we get that
\[
X_{A, \phi} = |W_{\mathcal{O}}(E)|^{-1} \sum_{w \in W_{\mathcal{O}}(E)} \text{Tr}((\theta_{w} \circ \sigma_{A})^{-1}, V_{A})X_{\text{ind}_{E_{1}^{\Sigma_{A}}}(E_{w}), \phi_{\Sigma_{A}}^{E}}
\]
for any \( F \)-equivariant admissible complex \((A, \phi_{A})\) with \( A \) a simple direct summand of \( K^{\nu} \).

3.19. Let \( A \) be an \( F \)-stable admissible complex on \( G \). By 3.12, there is a unique (up to \( G \)-conjugacy) cuspidal datum \((L, \Sigma, \mathcal{E})\) of \( G \) such that \( A \) is a direct summand of \( \text{ind}_{E}^{F}(\mathcal{E}) \). Hence from Lang's theorem, we may choose \((L, \Sigma, \mathcal{E})\) to be \( F \)-stable; we thus have a formula like 3.18 for any \( F \)-equivariant admissible complex \((A, \phi_{A})\) on \( G \).

3.20. Let \( I(G) \) be a set parametrizing the isomorphic classes of the \( F \)-stable admissible complexes on \( G \). For \( \iota \in I(G) \), let \((A_{\iota}, \phi_{\iota})\) be a corresponding \( F \)-equivariant admissible complex on \( G \). Then by the main result of [Lus87], the set \( \{X_{A, \phi} | \iota \in I(G)\} \) is a basis of \( C(G^{F}) \).

3.4 Twisted induction: a second definition

3.21. Let \( M \) be an \( F \)-stable Levi subgroup of \( G \) and let \( \mathcal{M} \) be the Lie algebra of \( M \). We define our twisted induction \( R_{\mathcal{M}}^{\nu} : C(M^{F}) \rightarrow C(G^{F}) \) on each element of a basis \( \{X_{A, \phi}, \iota \in I(\mathcal{M})\} \) of \( C(M^{F}) \) as in 3.20. Let \( \iota \in I(\mathcal{M}) \) and let \((L, \Sigma, \mathcal{E})\) be an \( F \)-stable cuspidal datum of \( M \) such that \( A_{\iota} \) is a direct summand of \( \text{ind}_{E}^{M}(\mathcal{E}) \). Let \( \phi : F^{\ast} \mathcal{E} \rightarrow \mathcal{E} \) be an isomorphism. For \( w \in W_{\mathcal{M}}(\mathcal{E}) \), let \( \theta_{w} \) be a non-zero element of \( w \in A_{w} \subset \text{End}(\text{ind}_{E}^{M}(\mathcal{E})) \). As in 3.18 we have
\[
X_{A_{\iota}, \phi_{\iota}} = |W_{\mathcal{M}}(E)|^{-1} \sum_{w \in W_{\mathcal{M}}(\mathcal{E})} \text{Tr}((\theta_{w} \circ \sigma_{A_{\iota}})^{-1}, V_{A_{\iota}})X_{\text{ind}_{E_{1}^{\Sigma_{A_{\iota}}}}(E_{w}), \phi_{\Sigma_{A_{\iota}}}^{E}}.
\]

Then we define \( R_{\mathcal{M}}^{\nu}(X_{A_{\iota}, \phi_{\iota}}) \) by
\[
R_{\mathcal{M}}^{\nu}(X_{A_{\iota}, \phi_{\iota}}) = |W_{\mathcal{M}}(E)|^{-1} \sum_{w \in W_{\mathcal{M}}(\mathcal{E})} \text{Tr}((\theta_{w} \circ \sigma_{A_{\iota}})^{-1}, V_{A_{\iota}})X_{\text{ind}_{E_{1}^{\Sigma_{A_{\iota}}}}(E_{w}), \phi_{\Sigma_{A_{\iota}}}^{E}}.
\]

Definition 3.24. The induction defined above is called geometrical induction.

Remark 3.25. (i) Note that the definition of \( R_{\mathcal{M}}^{\nu} : C(M^{F}) \rightarrow C(G^{F}) \) does not depend on the choice of the isomorphisms \( \phi_{\iota} \) with \( \iota \in I(\mathcal{M}) \). Indeed, let \( R_{\mathcal{M}}^{\nu} \) be the induction defined on another basis \( \{X_{A, \phi}, \iota \in I(\mathcal{M})\} \) and let \( \iota \in I(\mathcal{M})^{F} \). Since \( A_{\iota} \) is a simple perverse sheaf, there exists a constant \( c \in \overline{Q}_{l}^{\times} \) such that \( \phi_{\iota} = c \phi_{\iota}' \). Let \( \sigma_{A_{\iota}}' : V_{A_{\iota}} \rightarrow V_{A_{\iota}} \) be defined in terms of \( \phi_{\iota}', \phi_{\iota} \) as \( \sigma_{A_{\iota}} \) is defined in terms of \( \phi_{\iota} \). We thus have \( \sigma_{A_{\iota}} = c^{-1} \sigma_{A_{\iota}}' \). Hence for any \( w \in W_{\mathcal{M}}(\mathcal{E}) \), we have \((\theta_{w} \circ \sigma_{A_{\iota}})^{-1} = c(\theta_{w} \circ \sigma_{A_{\iota}}')^{-1} \). But since \( X_{A_{\iota}, \phi_{\iota}} = cX_{A, \phi_{\iota}'} \), this proves that \( R_{\mathcal{M}}^{\nu}(X_{A_{\iota}, \phi_{\iota}}) = cR_{\mathcal{M}}^{\nu}(X_{A, \phi_{\iota}'}). \) It is also clear that the induction \( R_{\mathcal{M}}^{\nu} \) does not depend on the choice of the isomorphisms \( \phi : F^{\ast} \mathcal{E} \rightarrow \mathcal{E} \) and on the choice of the isomorphisms \( \theta_{w} \in A_{w} \). The independent from the choice of the \( F \)-stable cuspidal data \((L, \Sigma, \mathcal{E})\) is a little bit more subtle, see remark before 3.28.

(ii) If $(M, \Sigma, \mathcal{E})$ is an $F$-stable cuspidal datum of $G$ together with an isomorphism $\phi : F^* \mathcal{E} \cong \mathcal{E}$, then
\[ R^G_M(X_{\mathcal{K}(\Sigma, \mathcal{E}), \phi}) = X_{\text{ind}^G_M(\mathcal{E}), \phi} \text{.} \]

(iii) Note that unlike Deligne-Lusztig induction, the definition of geometrical induction does not involve any parabolic subgroup of $G$.

3.26. The following fact is clear: assume that $\chi^G_M : C(M^F) \rightarrow C(G^F)$ is a $\bar{\mathbb{Q}}_L$-linear map such that for any $F$-stable cuspidal datum $(L, \Sigma, \mathcal{E})$ of $M$ and any isomorphism $\phi : F^* \mathcal{E} \cong \mathcal{E}$, we have $\chi^G_M(X_{\text{ind}^G_M(\mathcal{E}), \phi}) = X_{\text{ind}^G_M(\mathcal{E}), \phi}$, then $\chi^G_M = R^G_M$.

3.27. For any $F$-stable cuspidal datum $(L, \Sigma, \mathcal{E})$ of $M$ and any isomorphism $\phi : F^* \mathcal{E} \cong \mathcal{E}$, we have $R^G_M(X_{\text{ind}^G_M(\mathcal{E}), \phi}) = X_{\text{ind}^G_M(\mathcal{E}), \phi}$.

As a straightforward consequence of 3.27, we get that the geometrical induction is transitive and together with 3.26 we get that the formula 3.23 does not depend on the choice of the cuspidal datum $(L, \Sigma, \mathcal{E})$.

**Theorem 3.28.** Assume that $q$ is large enough so that the main result of [Lus90] applies. Then Deligne-Lusztig induction and geometrical induction coincide.

**Outlined of the proof:** Since Deligne-Lusztig induction is transitive, by 3.26, it is enough to prove that these two inductions coincide on the characteristic functions of $F$-equivariant cuspidal admissible complexes. Recall that if $(L, \Sigma, \mathcal{E}) = (L, z(L) + C, \mathbb{Q}_L \otimes \zeta)$ is an $F$-stable cuspidal datum of $G$ together with $\phi : F^* \mathcal{E} \cong \zeta$, the corresponding generalized Green function $G_{L, C, \zeta, \phi}$ is defined as the restriction to $G_{nL}$ of $X_{\text{ind}^G_M(\mathcal{E}), \phi}$ where $\phi^G$ is the canonical isomorphism induced by $1 \otimes \phi : F^* \mathcal{E} \cong \mathcal{E}$.

Now let $(L, \Sigma, \mathcal{E}) = (L, z(L) + C, m^* \mathcal{E} \otimes \zeta)$ be an $F$-stable cuspidal datum of $G$ and let $\phi : F^* \mathcal{E} \cong \zeta$ be an isomorphism. Let $\sigma, u \in G^F$ with $\sigma$ semi-simple and $u$ nilpotent such that $[\sigma, u] = 0$. Assume that $z \in G^F$ is such that $\text{Ad}(z^{-1}) \sigma \in z(L)$. Then put $L^u_z = z L_z^{-1}$ and $L_z^u = \text{Lie}(L_z^u)$. We have $\sigma \in z(L_z^u)$ and so $L_z^u$ is a Levi subgroup of $G^F(\sigma)$. Let $C_z^u = \text{Ad}(z)^C$ and let $(\zeta_x, \phi_x)$ be the inverse image of the $F$-equivariant sheaf $(\mathcal{E}, \phi)$ by $C_z^u \rightarrow \Sigma, v \mapsto \text{Ad}(z^{-1})(\sigma + v)$. Note that the irreducible local system $\zeta_x$ is isomorphic to $\text{Ad}(z^{-1})^* \zeta_x$. Then as in [Lus85, 8.5] we show the following character formula:

\[ (1) \quad X_{\text{ind}^G_M(\mathcal{E}), \phi}(\sigma + u) = |C^0_G(\sigma)|^{-1} \sum_{x \in G^F(\text{Ad}(z^{-1})) \sigma \in z(L)} G_{L_z^u, C_z^u, \zeta_x, \phi_x}(u) \text{.} \]

The main result of Lusztig [Lus90], giving (in the group case) a comparaison formula between the two-variable Green functions and the generalized Green functions, can be transferred to the Lie algebra case by mean of the isomorphism $\bar{G} : G_{nL} \rightarrow G_{nL}$. Using this comparaison formula together with the character formula (1), we show that $R^G_M(X_{\mathcal{K}(\Sigma, \mathcal{E}), \phi})(\sigma + u) := X_{\text{ind}^G_M(\mathcal{E}), \phi}(\sigma + u) = R^G_M(X_{\mathcal{K}(\Sigma, \mathcal{E}), \phi})(\sigma + u)$.

4 Fourier transforms and Deligne-Lusztig induction

In the following, for any $F$-stable Levi subgroup $L$ of $G$, the Fourier transforms $U^L : C(L^F) \rightarrow C(L^F)$ is taken with respect to $(\mu_{L^F \times L^F}, \Psi)$ as in the introduction. In [Let03b], the author has conjectured the following statement:
Conjecture 4.1. For any $F$-stable Levi subgroup $L$ of $G$, we have $\mathcal{F}^O \circ \mathcal{R}_2^O = \epsilon_{G \ell L} \mathcal{R}_2^O \circ \mathcal{F}_L$ where $\epsilon_G = (-1)^{\ell - \text{rank}(G)}$.

From now we assume that $p$ is acceptable and that $q$ is large enough so that Deligne-Lusztig induction coincides with geometrical induction. It is then clear that 4.1 is equivalent to:

**Conjecture 4.2.** For any $F$-stable Levi subgroup $L$ of $G$ supporting an $F$-equivariant cuspidal admissible complex $(K, \phi)$, we have $\mathcal{F}^O \circ \mathcal{R}_2^O(X_{K, \phi}) = \epsilon_{G \ell L} \mathcal{R}_2^O \circ \mathcal{F}_L(X_{K, \phi})$.

We denote by $\mathcal{F}^O : M_G(\mathfrak{g}) \to M_G(\mathfrak{g})$ the Deligne-Fourier transforms with respect to $(\mu, \Psi)$ that maps $K \in M_G(\mathfrak{g})$ onto $(pr_1)((pr_2)^*K \otimes \mu^* \mathcal{L}_\Psi)[\dim \mathfrak{g}]$ where $pr_1, pr_2 : G \times G \to G$ are the two projections. Recall that if $(K, \phi)$ is an $F$-equivariant complex, then there is a canonical isomorphism $\mathcal{F}^O : \mathcal{F}^O(K) \to \mathcal{F}^O(K)$ such that $X_{\mathcal{F}^OK, \mathcal{F}^O\phi} = (-1)^{\dim \mathfrak{g}} \mathfrak{g}^F \mathcal{F}^O(X_{K, \phi})$. If $L$ is a Levi subgroup of $G$ supporting a cuspidal pair, then by 1.4 any $F$-linear form on $z(L)$ is of the form $m_{\sigma} : z(L) \to \mathbb{F}$, $z \mapsto \mu(z, \sigma)$ for some $\sigma \in z(L)$. Now from [Lus87], for any cuspidal datum $(L, \Sigma, \zeta)$, we have $\mathcal{F}^O(K(\Sigma, \zeta)) \simeq K(\sigma + C, \overline{\mathbb{Q}}_l \mathfrak{z})$. A consequence we get that 4.2 is equivalent to:

**Conjecture 4.3.** For any $F$-stable Levi subgroup $L$ of $G$ supporting an $F$-equivariant cuspidal orbital complex $(K, \phi)$, we have $\mathcal{F}^O \circ \mathcal{R}_2^O(X_{K, \phi}) = \epsilon_{G \ell L} \mathcal{R}_2^O \circ \mathcal{F}_L(X_{K, \phi})$.

We want to prove that the statement 4.3 is actually equivalent to:

**Conjecture 4.4.** For any $F$-stable Levi subgroup $L$ of $G$ supporting an $F$-stable cuspidal pair $(C, \zeta)$ and any isomorphism $\phi : F^* \zeta \simeq \zeta$, we have $\mathcal{F}^O \circ \mathcal{R}_2^O(X_{K(C, \zeta), \phi}) = \epsilon_{G \ell L} \mathcal{R}_2^O \circ \mathcal{F}_L(X_{K(C, \zeta), \phi})$.

Note that 4.4 is a particular case of 4.3. The fact that 4.3 and 4.4 are equivalent comes from the following theorem:

**Theorem 4.5.** Let $(L, C, \zeta)$ be such that $L$ is an $F$-stable Levi subgroup of $G$ and $(C, \zeta)$ is an $F$-stable cuspidal pair of $L$. Then there is a constant $c \in \overline{Q}_l^X$ such that for any $\sigma \in z(L)^F$ and any $\phi : F^* \zeta \simeq \zeta$, we have $\mathcal{F}^O \circ \mathcal{R}_2^O(X_{K(C, \zeta), \phi}) = c \mathcal{R}_2^O \circ \mathcal{F}_L(X_{K(C, \zeta), \phi})$.

**About the proof of 4.5:** When the variety $z(L)$ is used as a parametrizing set of the cuspidal orbital complexes on $L$ of the form $K(\sigma + C, \overline{Q}_l \mathfrak{z})$, it is denoted by $S$. Let $Z_1 = S \times z(L)$ and $Z_2 = \{(z, z) : z \in z(L)\} \subset S \times z(L)$. Then $L$ acts on $Z_1 \times C$ and on $Z \times C$ by the adjoint action on $C$ and trivially on the first coordinate. Consider the following $F$-stable irreducible local systems: $\mathcal{L}_1 = (\mu_{z(L)})^* \mathcal{L}_\Psi \otimes \zeta \in I_{L}(Z_1, C)$, where $\mu_{z(L)}$ is the restriction of $\mu$ to $z(L) \times z(L)$, and $\mathcal{L}_2 = \mu_{z(L)}^* \mathcal{L}_\Psi \otimes \zeta \in I_{L}(Z_2, C)$. Let $\sigma \in z(L)^F$, we put $K_{1, \sigma} := K(z(L) + C, \mathcal{L}_1 \otimes \zeta)$ and $K_{2, \sigma} := K_{\sigma}$ as in 4.5. Clearly we have $(j_{\sigma, \mathcal{L}})^* K_1 = K_{1, \sigma}[\dim S]$ and $(j_{\sigma, \mathcal{L}})^* K_2 = K_{2, \sigma}[\dim S]$ where $j_{\sigma, \mathcal{L}} : L \to S \times L, z \mapsto (\sigma, z)$. Following [Wal01, Chapter 2], one has a functor $\text{ind}^S_{\mathcal{L}_1 \mathcal{L}_2, \phi} : M_L(S \times L) \to \mathcal{D}^b_{\text{c}}(S \times \mathfrak{g})$ generalizing the construction of ind$^S_{\text{c}}$, see 3.7. From [Wal01], the complexes $K_{1, \sigma}^{\mathcal{L}_1 \mathcal{L}_2} := \text{ind}^S_{\mathcal{L}_1 \mathcal{L}_2} (K_1)$ and $K_{2, \sigma}^{\mathcal{L}_1 \mathcal{L}_2} := \text{ind}^S_{\mathcal{L}_1 \mathcal{L}_2} (K_2)$ are simple perverse sheaves on $S \times \mathfrak{g}$. More precisely since $\{(z, z) \in Z_1 | z \in z(L)^{\text{reg}}\}$ and $\{(z, z) \in Z_2 | z \in z(L)^{\text{reg}}\}$ are non-empty, we can show
[Wal01], following the strategy of 3.9, that the complexes $K_{1}^{S \times G}$ and $K_{2}^{S \times G}$ are the perverse extensions of F-stable irreducible local systems on some F-stable locally closed subvarieties of G in particular $K_{1}^{S \times G}$ and $K_{2}^{S \times G}$ are both F-stable. Let $\phi_{1} : F^{*}(K_{1}) \simeq K_{1}$ and $\phi_{2} : F^{*}(K_{2}) \simeq K_{2}$ be two isomorphisms, and let $\phi_{1}^{S \times G} : F^{*} K_{1}^{S \times G} \simeq K_{1}^{S \times G}$ and $\phi_{2}^{S \times G} : F^{*} K_{2}^{S \times G} \simeq K_{2}^{S \times G}$ be the two isomorphisms induced respectively by $\phi_{1}$ and $\phi_{2}$. As in the proof of 3.28, one has a "character formula" [Let03b] expressing $X_{K_{1}^{S \times G}, \phi_{1}}^{S \times G}$ and $X_{K_{2}^{S \times G}, \phi_{2}}^{S \times G}$ in terms of the generalized Deligne functions. Hence if we define the Deligne-Lusztig induction $R_{S \times L}^{S \times G} : C(S^{F} \times L^{F}) \to C(S^{F} \times G^{F})$ by $R_{S \times L}^{S \times G}(f)(t, x) = |L|^{-1} \sum_{y \in L^{F}} S_{C^{G^{F}}(x, y)} f(t, y)$ where $S_{C^{G^{F}}(x, y)}$ is as in section 2, then we show that

$$R_{S \times L}^{S \times G}(X_{K, \phi}) = X_{K_{1}^{S \times G}, \phi_{1}}^{S \times G} \quad \text{and} \quad R_{S \times L}^{S \times G}(X_{K_{2}, \phi_{2}}^{S \times G}) = X_{K_{2}^{S \times G}, \phi_{2}}^{S \times G}.$$

Now one has a Fourier transform $F^{S \times G} : C(S^{F} \times G^{F}) \to C(S^{F} \times G^{F})$ given by $F^{S \times G}(f)(t, x) = |G^{F}|^{-1} \sum_{y \in G^{F}} \Psi(\mu(y, x)) f(t, y)$ and a Deligne-Fourier transforms $F^{S \times G} : M_{0}(S \times G) \to M_{0}(S \times G)$ given by $F^{S \times G}(K) = (p_{1})_{!}((p_{2})^{*}K \otimes (p_{2})^{*}(\mu^{*}L_{0}))[\dim G]$ where $p_{13}, p_{12} : S \times G \to S \times G$ and $p_{23} : S \times G \to S \times G$ are the projections. We have the following relation: if $(K, \phi)$ is an F-equivariant complex on $S \times G$, then $\phi$ induces an isomorphism $F(\phi) : F^{*}(F^{S \times G}K) \simeq F^{S \times G}K$ such that

$$F^{S \times G}(R_{S \times L}^{S \times G}(X_{K, \phi})) = c R_{S \times L}^{S \times G}(F^{S \times G}(X_{K, \phi})).$$

Restricting this equality to $\{\sigma\} \times G^{F}$, we get the required result.

4.6. The previous equivalences shows that, under the assumption "p is acceptable and g is large", we have reduced the study of 4.1 to that of 4.4.

4.7. Now let $L$ be an F-stable Levi subgroup of G supporting an F-stable cuspidal pair $(C, \zeta)$. Since the group $W_{0}(\zeta)$, defined as in 3.2 with $\zeta$ instead of $\zeta$, is nothing but $W_{0}(L) := N_{G}(L)/L$ [Lus84, 9.2], we get that there exists an F-stable G-split Levi subgroup $L_{0}$ of $G$ which is G-conjugate to $L$, and $\psi \in W_{0}(L_{0})$ such that $(L, C, \zeta)$ is of the form $(L_{0}, C_{0}, \zeta_{0})$, see 3.13. Put $\Sigma = \zeta(L) + C, \Sigma_{0} = \zeta(L_{0}) + C_{0}, \zeta = \mathbb{Q} \otimes \zeta$ and $\Sigma_{0} = \mathbb{Q} \otimes \zeta_{0}$. From [Lus87], there exist two constants $\gamma_{0} \in \mathbb{Q}^{*}$ such that for any isomorphisms $\phi : F^{*}(\zeta) \simeq \zeta_{0}$ and $\phi_{0} : F^{*}(\zeta_{0}) \simeq \zeta$, we have

$$F^{C}(X_{K(C, \zeta), 18\phi_{0}}) = \gamma_{0} X_{K(C, \zeta), \phi_{0}}$$

and $F^{C}(X_{K(C, \zeta), 18\phi_{0}}) = \gamma_{0} X_{K(C, \zeta), \phi_{0}}$. The constant $\gamma_{0}$ is called the Lusztig's constant attached to $(L, C, \zeta)$ with respect to $F$. Let $\psi : W_{0}(L_{0}) \to \mathbb{Q}$ be the sign character of $W_{0}(L_{0})$.

**Proposition 4.8.** We have:

$$F^{C} \circ R_{L}^{C}(X_{K(C, \zeta), 18\phi_{0}}) = \epsilon_{C} \mathbb{C} F^{C}(X_{K(C, \zeta), \phi_{0}})$$

if and only if $\gamma = \epsilon_{C} \mathbb{C} \mathbb{E}(\psi) \gamma_{0}$.

The proof of 4.8 uses the fact that Harish-Chandra induction commutes with Fourier transforms; this has been proved at first by Lusztig [Lus87] in the case of cuspidal functions and then
by Lehrer in full generality [Leh96]. With the above notation, put $\tilde{\gamma} = \eta_L \sigma_L \gamma$ with $\eta_L = \epsilon_L \epsilon_L^*$ and $\sigma_L = (-1)^{rk(L)} z$. Then the equality $\gamma = \epsilon_L \epsilon_L \sigma_L (w) \gamma_0$ of 4.8 is equivalent to $\tilde{\gamma} = \gamma_0$. We call $\tilde{\gamma}$ the modified Lusztig's constant attached to $(L, C, \zeta)$ with respect to $F$.

From 4.6 and the proposition 4.8 we deduce the following theorem:

**Theorem 4.9.** Assume that $p$ is acceptable for $G$ and that $q$ is large enough so that Deligne-Lusztig induction coincides with geometrical induction. Then the following assertions are equivalent:

(i) The statement 4.1 holds.

(ii) For any $F$-stable triple $\iota = (L, C, \zeta) \in \mathfrak{w}$ and that Deligne-Lusztig induction coincides with geometrical induction. Then the following assertions are equivalent:

(i) The statement 4.1 holds.

(ii) For any $F$-stable triple $\iota = (L, C, \zeta)$ with $L$ a proper $G$-split Levi subgroup of $G$ and $(C, \zeta)$ a cuspidal pair on $L$, the modified Lusztig's constant attached to $\iota$ does not depend on the Frobenius $w^F$ with $w \in W_G(L)$.

5. **Lusztig's constants**

**Remark 5.1.** The Lusztig constant attached to an $F$-stable maximal torus $T$ is equal to $(-1)^{rk(C)} q^{14(q)-1}$, hence does not depend on the Frobenius $w^F$ for $w \in W_G(T)$.

5.2. The statement 4.9(ii) can be easily reduced to the case where $G$ is simple. Then using the classification of the cuspidal data of simple algebraic groups [Lus84], we see that 4.9(ii) reduces to:

**Conjecture 5.3.** Assume that:

(i) $G$ is either semi-simple of type $A_n$ or simple of type $B_n$, $C_n$, or $D_n$.

(ii) $p$ is very good for $G$.

(iii) $G$ supports an $F$-stable cuspidal pair $(C, \zeta)$.

Then the modified Lusztig's constants attached to $(C, \zeta)$ do not depend on the $\mathbb{F}_q$-structure on $G$ for which the induced Frobenius endomorphism stabilizes $(C, \zeta)$.

5.4. The statement 5.3 is clear if $G$ is of type either $B_n$ or $C_n$ since in that case any Frobenius endomorphism on $G$ acts trivially on the root system of $G$. From now we assume that $G$ is simple and supports an $F$-stable cuspidal pair $(C, \zeta)$. We also assume that $p > 3(h^G_\zeta - 1)$ where $h^G_\zeta$ is the Coxeter number of $G$. In the following we give a formula for the Lusztig's constants attached to $(C, \zeta)$.

5.5. We fix an element $u_o \in C^F$ where $C$ is as in 5.3. Under our assumption, we can use Dynkin-Kostant-Springer-Steinberg's theory on nilpotent orbits on $G$. Hence there exists an $F$-stable $Z$-grading $G = \bigoplus_i G(i)$ of $G$ with the following properties:

(i) $u_o \in G(2)$.

(ii) $P = \oplus_{i \geq 2} G(i)$ is the Lie algebra of an $F$-stable parabolic subgroup $P$ of $G$ and $L = G(0)$ is the Lie algebra of an $F$-stable Levi subgroup $L$ of $P$.

(iii) $G(2)$ is stable under the adjoint action of $L$ and $O^L_{u_o}$ is dense in $G(2)$.

(iv) $U_P = \oplus_{i \geq 0} G(i)$.

(v) The group $C_G(u_o)$ is unipotent and connected, and the group $C_G(u_o)$ is the semi-direct product of $C_L(u_o)$ and $C_G(u_o)$ as an algebraic group.

(vi) We have $O^L_{u_o} \cap (\oplus_{i \geq 2} G(i)) = O^L_{u_o}$.

(vii) The pair $(C, \zeta)$ being cuspidal, by [Lus84, 2.8] the element $u_o$ is distinguished i.e. the map $\text{ad}(u_o) : G(0) \rightarrow G(2)$ is bijective. Hence we have $G(i) = \{0\}$ if $i$ is odd i.e. $U_P = \oplus_{i \geq 0} G(i)$, and from (iii) we deduce that $C^F_L(u_o) = \{0\}$. 

5.6. We now define the generalized Gelfand–Graev functions following [Kaw85]. Let $A_G(u_o) := C_G(u_o)/C_G^o(u_o)$ and let $H^1(F, A_G(u_o))$ be the group of $F$-conjugacy classes of $A_G(u_o)$. By setting that $1 \in H^1(F, A_G(u_o))$ corresponds to the $G^F$-orbit of $u_o$, we have a well-defined parametrization of the $G^F$-orbits in $C^F$ by $H^1(F, A_G(u_o))$. From 5.5(v), we have $A_G(u_o) \simeq A_L(u_o)$, hence for $z \in H^1(F, A_G(u_o)) \simeq H^1(F, A_L(u_o))$, we can choose an element $u_z \in G(2)^F$ which is in the $G^F$-orbit of $C^F$ corresponding to $z$. Let $U_p = \bigoplus_{(i < 2)} G(i)$, then for each $z \in H^1(F, A_L(u_o))$, we define a linear additive character $\Psi_z : (U_p^{-1})^F \rightarrow \overline{\mathbb{Q}}_l$ by $\Psi_z(u) = \Psi(\mu(u_z, u))$ where $(\mu, \Psi)$ is as in section 4. The corresponding generalized Gelfand–Graev function $\Gamma_z : G^F \rightarrow \overline{\mathbb{Q}}_l$ is defined by:

$$\Gamma_z(z) = [U_p^{-1}] \sum_{g \in G^F : \mu(g) = H^1(F, A_L(u_o))} \Psi_z(\text{Ad}(g)z).$$

The $G^F$-equivariant irreducible local system $\zeta$ corresponds to a unique $F$-stable irreducible character (denoted again by $\zeta$ of $A_G(u_o)$ which can be extended to a character on the semi-direct product $A_G(u_o) \rtimes (F)$ where $(F)$ is the cyclic group generated by the Frobenius $F$. The restriction to $A_G(u_o)$ of this extended character is constant on the $A_G(u_o)$-orbits and so leads to a unique function $\tilde{\zeta}$ on $H^1(F, A_G(u_o)) \simeq H^1(F, A_L(u_o))$. We then define a nilpotently supported function $\Gamma_\zeta : G^F \rightarrow \overline{\mathbb{Q}}_l$ by:

$$\Gamma_\zeta(z) = \sum_{z \in H^1(F, A_L(u_o))} |z| \tilde{\zeta}(z) \Gamma_z.$$  

5.7. By [Lus92, 7.6], the function $\Gamma_\zeta$ is proportional to the characteristic function of the $F$-equivariant perverse sheaf $(K(C, \zeta), \phi)$ for any $\phi$. As a consequence we get that:

$$\mathcal{F}^G(\Gamma_\zeta) = \gamma^F \Gamma_\zeta$$

where $\gamma^F$ denotes the Lusztig’s constant attached to $(C, \zeta)$ with respect to $F$. From the classification of the distinguished parabolic subgroups of $G$, we can verify that the longest element $w_0$ of $W_G(T)$ (with $T$ a maximal torus of $L$) normalizes $L$ and $\text{Ad}(w_0)$ maps $G(2)$ onto $G(-2)$. As a consequence $G_u \cap G(-2) \neq \emptyset$ and any element of $G_u \cap G(-2)$ is distinguished with associated parabolic subgroup $P' = \text{L}_P$. Let $u_0^* \in G_u \cap G(-2)^F$. From [Lus92, 6.13] we have $\mathcal{F}^G(\Gamma_\zeta)(u_0^*) = \tilde{\zeta}(1)|1||C_L(u_0)^F|q^{-\dim G_u^{\text{red}}} q^{\dim G_u^{\text{red}}}$. Hence by 5.5(v), we deduce that:

$$\gamma^F = \tilde{\zeta}(1)|1||C_L(u_0)^F|q^{-\dim G_u^{\text{red}}} q^{\dim G_u^{\text{red}}}.$$  

Hence the computation of $\gamma^F$ reduces to that of $\Gamma_\zeta(u_0^*)$. For any $z \in H^1(F, A_L(u_o))$ we have:

$$\Gamma_z(u_0^*) = [U_p^{-1}] \sum_{g \in F^{-1}} \Psi_z(g) = \sum_{g \in L^F} \Psi_z(\text{Ad}(g)u_0^*).$$

These equalities come from 5.5(vi), 5.5(iii) where $(u_0, P)$ is replaced by $(u_0^*, P')$, and the fact that the restriction of $\Psi_z$ to $\bigoplus_{i = -2} G(i)$ is trivial. We thus get that:

$$\Gamma_\zeta(u_0^*) = \sum_{z \in H^1(F, A_L(u_o))} |z| \tilde{\zeta}(z) \sum_{i \in L^F} \Psi_z(\text{Ad}(l)u_0^*).$$

Let $\mathcal{L}_L : L \rightarrow L$, $t \rightarrow t^{-1}F(t)$ be the Lang map. Then we have a surjective map

$$\overline{\mathcal{L}} : \mathcal{L}_L^{-1}(C_L(u_0))/C_L(u_0) \rightarrow H^1(F, C_L(u_0)) \simeq H^1(F, A_L(u_o)).$$
which maps $tC_{L}(u_{o})$ onto the $F$-conjugacy class of $t^{-1}F(t)$. For $z \in H^{1}(F, A_{L}(u_{o}))$, let $l_{z} \in L$ be such that $l_{z}^{-1}F(l_{z}) = \tilde{z}$ where $\tilde{z} \in C_{L}(u_{o})$ is a representative of $z$, and $u_{z} = \text{Ad}(l_{z})u_{o}$. Then we have a well-defined map $\varphi_{z} : L^{F} \to \mathcal{L}_{L}^{-1}(z)$ given by $t \mapsto tl_{z}C_{L}(u_{o})$. This map is clearly surjective and its fibers are all of cardinality $\alpha_{z} = |\{h \in C_{L}(u_{o})|h^{-1}zF(h) = \tilde{z}\}|$.

For $g \in \mathcal{L}_{L}^{-1}(C_{L}(u_{o}))$ and $x \in (U_{P}^{F})^{F}$, define $\Psi_{\sigma}(x) := \Psi(\mu(\text{Ad}(g)u_{o}, x)) = \Psi_{\sigma}(\mu(u_{o}, \text{Ad}(g^{-1}(x)))) = \Psi_{\sigma}(\text{Ad}(g^{-1})x)$. We thus have:

$$\sum_{t \in L^{F}} \Psi_{\sigma}(\text{Ad}(t)u_{o}^{*}) = \sum_{t \in L^{F}} \epsilon_{t} \Psi_{\sigma}(u_{o}^{*}) = \alpha_{\sigma} \sum_{l \in C_{L}(u_{o})} l \Psi_{\sigma}(u_{o}^{*}).$$

We finally deduce that:

$$\Gamma_{\sigma}(u_{o}^{*}) = |C_{L}(u_{o})| \sum_{l \in \mathcal{L}_{L}^{-1}(C_{L}(u_{o}))/C_{L}(u_{o})} \xi_{l}(\mathcal{L}(l)) \Psi_{\sigma}(u_{o}^{*}).$$

Indeed we have $\alpha_{\sigma}|z| = |C_{L}(u_{o})|$ since by 5.5(vii), we have $A_{L}(u_{o}) = C_{L}(u_{o})$. Note that $\mathcal{L}_{L}^{-1}(C_{L}(u_{o}))/C_{L}(u_{o}) = (L/C_{L}(u_{o}))^{F}$. We define the quantity:

$$\sigma_{\zeta} := \xi(1)^{-1} \sum_{l \in (L/C_{L}(u_{o}))^{F}} \xi(\mathcal{L}(l)) \mathcal{P}_{\sigma}(\text{Ad}(l)u_{o})$$

where $\Psi_{\sigma}^{*}$ is the additive character of $G(2)F$ defined by $\Psi_{\sigma}^{*}(v) = \Psi(\mu(u_{o}^{*}, v))$. Note that $\sigma_{\zeta}$ does not depend on the choice of the extension of $\zeta$ on $A_{G}(u_{o}) \rtimes \langle F \rangle$. Since $|1||C_{L}(u_{o})^{F}| = |C_{L}(u_{o})|$, we thus have:

**5.8.**

$$\gamma^{F} = \sigma_{\zeta}^{-1} q^{d}$$

where $d = \dim C_{L}(u_{o}) - \dim C_{L}(u_{o})$.

From 5.8, we see that to prove 5.3, we are reduced to prove the analogous statement for the constants $\sigma_{\zeta}$. The constant $\sigma_{\zeta}$ is computed explicitly in [DLM97] when $G$ is of type $A_{n}$ from which we can verify the required property. Hence from 4.9, 5.4 and the computation of the Lusztig constants in the case of $SO_{n}(F)$ [Wal01], we deduce the two following theorems:

**Theorem 5.9.** Assume that $p > 3(h_{G}^{G} - 1)$ and that $q$ is large enough so that Deligne-Lusztig induction coincides with geometrical induction. Assume moreover that every simple component of $G/Z_{G}^{0}$ of type $D_{n}$ is either the special orthogonal group $SO_{2n}(F)$ or the adjoint group of type $D_{n}$, then 4.1 holds.

**Theorem 5.10.** Assume that $p$ and $q$ are as in 5.9. Let $L$ be an $F$-stable Levi subgroup of $G$. Let $f$ be the characteristic function of an $F$-equivariant $L$-equivariant simple perverse sheaf $(K, \phi)$ which is supported by the Zariski closure of an $L$-orbit of $L$. If $K$ is a direct summand of the parabolic induction of a cuspidal orbital perverse sheaf supported by a regular orbit, then

$$\mathcal{F} = \epsilon_{G} \epsilon_{L} \mathcal{F}^{G} = \epsilon_{G} \epsilon_{L} \mathcal{F}^{L}(f).$$

Now a result of [Sho95] says that [Lus90, 1.14], which gives a relation between generalized Green functions and two-variable Green functions, holds for any $q$ whenever the cuspidal Levi subgroup is a maximal torus. Hence from 5.1, we have:
Theorem 5.11. The statement 5.10 holds for $p$ acceptable and any $q$ whenever the complex $K$ is a direct summand of the parabolic induction of a cuspidal orbital perverse sheaf on the Lie algebra of a maximal torus of $G$.

If $G$ is either $GL_n(F)$, or a simple group of type $E_8$, $F_4$ or $G_2$, and if $p$ is good for $G$, then the only proper Levi subgroups which support a cuspidal pair are the maximal tori. Hence from 5.11 we have:

Corollary 5.12. Assume that $G$ is either $GL_n(F)$ or a simple group of type either $E_8$, $F_4$ or $G_2$, and that $p$ is good for $G$, then 4.1 holds.
