(Received September 30, 1969)

ABSTRACT

Rotational velocities of 3951 stars are compiled from various sources which are currently available. The Slettebak system of observation is adopted as the standard for the calibration, and each observational datum is converted into this system. Rotational velocities and spectral types of the stars are given in the attached table together with some other informations.

Since the pioneering work by Shajn and Struve (1929), many people have observed the rotational velocities of stars. The first extensive study on the subject was carried out by Westgate (1933a, 1933b, and 1934). Later Huang (1953), Slettebak (1949, 1954, 1955, and 1956), and Slettebak and Howard (1955) made a series of observations and discussed the distribution of the rotational velocities among the stars with various spectral types. Since that time, the discussions have shifted to specific problems, such as rotational velocities of cluster members, of binaries, of peculiar stars, of variable stars, and so on. Details on these points are given in Table 1.

On the other hand, in order to discuss the problems statistically, it seems preferable to compile as many observational data as possible in an unbiased form. Since Boyarchuk and Kopylov (1964) first made a compilation of the rotational velocities of 2558 stars, there have been many new observations with higher accuracy. The total number of stars whose rotational velocities have been observed has now increased by more than fifty per cent compared to the number of stars in the Boyarchuk-Kopylov list. The purpose of this paper is to make a supplementary compilation to their work and to prepare the basic data for some statistical discussions. We have gathered as many data as possible from various sources available up to 1967 and from recent papers prepared by Slettebak (1968), Slettebak, Wright, and Graham (1968), and by Palmer, Walker, Jones, and Wallis (1968) who have kindly offered us their observational data in advance of publication.

As is well known, works by Slettebak (1949, 1954, 1955, and 1956) and Slettebak and Howard (1955) had covered a wide range of spectral types with a consistent system of observation, and the system has been adopted by many observers as the calibration standard. In the older observations, there are many stars in common to those observed by above authors. Hence it seems preferable to calibrate these data in

Slettebak's system in order to get a homogeneous set of data. The fact that this standard system is not valid for very rapidly rotating stars (cf. Hardorp and Strittmatter 1968, Stoeckley 1968a, and Stoeckley 1968b) is not considered here since a sequence of standard stars including such objects has not been well established.

All sources used for the present compilation are listed in Table 1. Each column gives (1) the authors, (2) the spectral types of stars, or the names of clusters observed, (3) the number of stars, (4) the dispersion of the spectrographs, (5) the absorption lines used to determine the rotational velocities, (6) the weight (see the below), and (7) the reference number for the identification of sources.

Some authors did not give the rotational velocities explicitly. Wilson (1966) represented the magnitude of rotation by a series of numerical indices ranging from 1 to 5. The transformation from this system to the actual velocities was carried out by Kraft (1967b) using the calibration table given by Wilson (1966). We adopted his values in the present compilation. When line widths were given instead of rotational velocities (Westgate 1933a and 1933b, and Huang 1953), we used a conversion formula given by Huang (1953).

Transformation into the Slettebak system can be made graphically with the use of commonly observed stars. Calibration curves for individual authors were constructed by means of the least square method. A linear relation was found to be sufficient in most cases, except in the case of Herbig and Spalding (1955), whose data seemed to deviate intrinsically from any linear relations, as was also noted by Slettebak (1955). For these data, we used a calibration curve with a quadratic form.

In the case of Smith and Struve (1944), there seems to exist no systematic differences from the standard system as long as seven common stars are concerned. However, Anderson, Stoeckly, and Kraft (1966) pointed out that the agreement was quite fortuitous, and that there were rather large systematic differences when compared with Abt and Hunter's (1962) data which were calibrated to Slettebak system with an excellent internal consistency. Fortunately, the list given by Abt and Hunter (1962) contains many stars observed by Smith and Struve (1944). We therefore adopted the former's data for the calibration standard in this case.

In transforming Huang's (1953) data, we derived separate calibration curves according to the spectral types of the stars and to the types of the absorption lines measured, because the line widths are dependent not only on the rotational velocity but also on the temperature and on the apparent abundance of the element. We divided them into five groups: (a) B-type stars in which helium line was measured, (b) B-type stars in which magnesium line was measured, (c) A-type stars, (d) F-type stars, and (e) G- and later types.

When there were few stars common to Slettebak's ones, we adopted the raw data, assigning relatively low weight to them.

We assigned a weight for each observation according to the quality of the instrument used, the individual errors, and the standard deviation in the calibration process. They are listed in the 6th column of Table 1. The adopted value of the rotational velocity of a star is the weighted mean of all the observations for the star.

In Table 2, the stars are arranged in order of right ascension. Columns 1, 2, and 3 in this table are current numbers, HD or BD numbers, and the star names, respectively. MK or HD spectral types are given in column 4. They are taken from the list by Jaschek, Conde, and Sierra (1964), from Appenzellar (1967), from Hoffleit (1964), and from sources cited in Table 1. We often found discrepancies

in the spectral types and luminosity classes among the authors. The MK types appearing in the present table are those which are in best agreement among various authors. The reader may refer to the catalog of MK spectral types compiled by Jaschek, Conde, and Sierra (1964).

In column 5, the adopted rotational velocities are given. The following points should be noted : (1) The weight was reduced by half or less from the originally assigned one when the author notes the values as uncertain; (2) for a very slow rotator we emphasized those observations with higher dispersions, and the data with very low dispersions were sometimes omitted; (3) the data which showed extreme discrepancies compared with the others were generally omitted; (4) in binary systems, some authors resolved them into the components, while others did not. We omitted the latter's data if it was not discernible to which component the data were referred. All sources thus omitted are denoted by the asterisked reference numbers in the last column of the table.

Finally, columns 6 and 7 give, respectively, remarks concerning the identification of the star and the reference numbers of sources used in this compilation (see the last column of Table 1).

ACKNOWLEDGEMENT

We are grateful to Professors S. Ueno, T. Shimizu, and M. Nishida for their helpful discussions and continuous encouragements. Thanks are due to professors Y. Sato and J. Jugaku for supplying us with valuable literatures, and to Dr. E. N. Walker for sending us his observational data. We are also indebted to Dr. W. M. Irvine for reading the manuscript of the present paper.

All computations were made with HITAC 5020 Computer at the Kyoto University Computer Center.

Note to Table I.

* Of 93 stars observed by van Dien (1948), individual data are given only for 18 stars.

** Most of the data appearing in Ringuelet-Kaswalder's (1963) list are taken from other sources.

NOTE TO THE TABLE 2

Although most of the star names in the 3rd column of this table is taken from Bayer or Flamsteed designation, another designations are sometimes adopted.

REMARKS

1. Hertzprung (1947) number for the Pleiades members.
 2. Identification of the star is given by Hayford (1932).
 3. HD number of this star is inferred from the position, the spectral type, and the other parameters.
 4. Identification of the star is given by Hayford (1932).
 5. Klein-Wassink (1927) number for the Praesepe cluster.
 6. Trumpler (1938) number for the Coma cluster.
 7. Kopff (1943) number for the IC 4665 members.
 8. Ebbighausen (1940) number for the M39 members.
- *(No. 2786) This star is denoted as HD 153987 by Wilson (1966). However, on the basis of several parameters given in his table, we presume this star to be HD 153897.
