THE STRUCTURE AND MEASURE OF SINGULAR SETS OF SOLUTIONS TO ELLIPTIC EQUATIONS

QING HAN

For a harmonic function in an open set in $\mathbb{R}^2$, the subset of critical points in the nodal set is exactly the singular part of the nodal set. For this reason, this subset of critical points is called the singular set. It is well known that the singular set of a 2-dimensional harmonic function is isolated. Around each point in the singular set, the nodal set consists of finitely many analytic curves intersecting at this point, forming equal angles. In fact, the number of singular points can be estimated in terms of the growth of the harmonic function. One way to do this is to identify $\mathbb{R}^2$ as $\mathbb{C}$ and then the singular set can be identified as the zero set of some holomorphic function.

In this note, we shall study the critical nodal sets, or the singular sets, of solutions to homogeneous elliptic equations of the second order. To be specific, we shall study the structure and the size of the critical nodal sets. Throughout the paper, we shall assume that $u$ is at least a nonzero $C^2$ solution in $B_1 \subset \mathbb{R}^n$ to the following elliptic equation

\begin{equation}
\mathcal{L}u \equiv \sum_{i,j=1}^{n} a_{ij}(x) \partial_{ij}u + \sum_{i=1}^{n} b_i(x) \partial_i u + c(x) u = 0,
\end{equation}

where the coefficients satisfy the following assumptions

\begin{equation}
\sum_{i,j=1}^{n} a_{ij}(x) \xi_i \xi_j \geq \lambda |\xi|^2, \quad \text{for any } \xi \in \mathbb{R}^n, \ x \in B_1,
\end{equation}

\begin{equation}
\sum_{i,j=1}^{n} |a_{ij}(x)| + \sum_{i=1}^{n} |b_i(x)| + |c(x)| \leq \kappa, \quad \text{for any } x \in B_1,
\end{equation}

and

\begin{equation}
\sum_{i,j=1}^{n} |a_{ij}(x) - a_{ij}(y)| \leq K|x - y|, \quad \text{for any } x, y \in B_1,
\end{equation}

for some positive constants $\lambda, \kappa$ and $K$. The Lipschitz condition (0.3) for the leading coefficients is essential. It implies the unique continuation for the operator $\mathcal{L}$. In other words, if a solution $u$ to (0.1) vanishes to an infinite order at a point in $B_1$, then $u$ is identically zero. For details, see [7].

The author is partially supported by an NSF grant.
Now we define the nodal set and the singular set by
\[ N(u) = \{ p \in B_1; u(p) = 0 \}, \]
\[ S(u) = \{ p \in B_1; |\partial u(p)| = 0 \}. \]
By the implicit function theorem, \( N(u) \setminus S(u) \) is an \((n - 1)\)-dimensional hypersurface, at least locally. In this note, we shall study \( S(u) \). We shall prove that \( S(u) \) is \((n - 2)\)-dimensional and its \((n - 2)\)-dimensional measure is bounded in terms of the frequency.

1. The Structure of Singular Sets

We first begin with a simple case.

**Lemma 1.1.** Let \( a_{ij}, b_i, c \) be smooth in \( B_1 \subset \mathbb{R}^n \) and \( u \) be a smooth solution to (0.1) in \( B_1 \). Then \( S(u) \) is contained in a countable union of \((n - 2)\)-dimensional smooth manifolds.

**Proof.** For any \( p \in B_1 \), we set the vanishing order \( O(p) \) of \( u \) at \( p \) as
\[ O(p) = O_u(p) = \{ d; \partial^\nu u(p) = 0 \text{ for any } |\nu| < d, \]
\[ \partial^{\nu_0} u(p) \neq 0 \text{ for some } |\nu_0| = d \}. \]
Obviously, \( O(p) \geq 2 \) for \( p \in S(u) \). For any \( d \geq 2 \), we set
\[ S_d(u) = \{ p \in B_1; O(p) = d \}. \]
Then we have
\[ S(u) = \bigcup_{d \geq 2} S_d(u). \]
This is a finite union by the unique continuation. We shall prove that each \( S_d(u) \) is \((n - 2)\)-dimensional for each fixed \( d \geq 2 \).

For any \( p \in S_d(u) \), there exists a \( |\beta| = d - 2 \) such that \( \partial^\beta v(p) \neq 0 \) for \( v = \partial^\beta u \). Now applying \( \partial^\beta \) to (0.1) and evaluating at \( p \), we obtain
\[ \sum_{i,j=1}^n a_{ij}(p) \partial_{ij} v(p) = 0. \]
First, the Hessian matrix \( (\partial^2 v(p)) \) has a nonzero eigenvalue. Next, we may diagonalize
\[ (\partial^2 v(p)) = \text{diag}(\lambda_1, \ldots, \lambda_n). \]
Then we have
\[ a_1(p)\lambda_1 + \cdots + a_n(p)\lambda_n = 0, \]
for some positive constants \( a_1(p), \ldots, a_n(p) \). By assuming \( \lambda_1 \neq 0 \), we have another nonzero eigenvalue and hence we may assume \( \lambda_2 \neq 0 \). Note
\[ \partial \partial_1 v(p) = (\lambda_1, 0, \ldots, 0), \quad \partial \partial_2 v(p) = (0, \lambda_2, 0, \ldots, 0). \]
By applying the implicit function theorem to \( \partial_1 v \) and \( \partial_2 v \), we conclude that \( \{ \partial_1 v = 0, \partial_2 v = 0 \} \) is an \((n - 2)\)-dimensional manifold in a neighborhood.
of \( p \). Obviously, this manifold contains \( S_d(u) \) in a neighborhood of \( p \). This finishes the proof. \( \square \)

Now, we shall discuss nonsmooth solutions. First, we shall generalize the notion of the vanishing order. Suppose \( u \) is a solution to (0.1). By the unique continuation, for any \( p \in B_1 \) there exists an integer \( d \) such that

\[
\limsup_{x \to p} \frac{|u(x)|}{|x-p|^d} < \infty,
\]

\[
\limsup_{x \to p} \frac{|u(x)|}{|x-p|^{d+1}} = \infty.
\]

Bers [1] proved that there exists a nonzero homogeneous polynomial \( P \) of degree \( d \) such that

\[
u(x) = P(x - p) + o(|x - p|^d).
\]

Naturally the integer \( d \), the degree of the polynomial \( P \), is called the vanishing order of \( u \) at \( p \), denoted by \( O(p) \) or \( O_u(p) \). For convenience we call the nonzero homogeneous polynomial the leading polynomial of \( u \) at \( p \). We have following results concerning the vanishing order and the leading polynomial.

**Lemma 1.2.** Let \( u \) be a \( C^2 \) solution of (0.1) with (0.2) and (0.3) and \( P \) be the leading polynomial of \( u \) at 0, with \( d = \deg P \). Then there hold for any \( \alpha \in (0, 1) \)

\[
\sum_{i,j=0}^{n} a_{ij}(0) \partial_{ij} P = 0 \quad \text{in } \mathbb{R}^n,
\]

\[
|P(x)| \leq C \|u\|_{L^2(B_1)} |x|^d \quad \text{in } B_1,
\]

\[
|u(x) - P(x)| \leq C \|u\|_{L^2(B_1)} |x|^{d+\alpha} \quad \text{in } B_{\frac{1}{2}}(0),
\]

and

\[
\sum_{i=1}^{2} r^i \|D^i(u - P)\|_{L^2(B_r)} \leq C \|u\|_{L^2(B_1)} r^{d+\alpha+\frac{\kappa}{2}} \quad \text{for any } r \leq \frac{1}{2},
\]

where \( C \) is a constant depending only on \( n, d, \lambda, \alpha, \kappa \) and \( K \).

**Lemma 1.3.** Suppose that \( \{\mathcal{L}_k\}_{k=0}^\infty \) is a family of elliptic operators in \( B_1 \) of the form (0.1) satisfying (0.2) and (0.3) and that \( u_k \) is a \( C^2 \) solution of \( \mathcal{L}_k u_k = 0 \) in \( B_1 \) for \( k = 0, 1, 2, \cdots \). Suppose that \( \mathcal{L}_k \to \mathcal{L}_0 \) in the sense that the corresponding coefficients converge uniformly and that \( u_k \to u_0 \) in \( L^\infty(B_1) \). Then there holds

\[
(1.2) \quad \limsup_{k \to \infty} O_{u_k}(0) \leq O_{u_0}(0).
\]

If, in addition, \( O_{u_k}(0) = d \) and \( P_k \) is the leading polynomial of \( u_k \) at 0 for \( k = 1, 2, \cdots \), then the following conclusions hold:
(i) if $O_{u_0}(0) > d$, then
$$P_k \to 0 \text{ uniformly in } B_1 \text{ as } k \to \infty;$$
(ii) if $O_{u_0}(0) = d$, then
$$P_k \to P_0 \text{ uniformly in } B_1(0) \text{ as } k \to \infty,$$
where $P_0$ is the leading polynomial of $u_0$ at 0.

The proof is quite complicated. In [9], we first proved Lemma 1.2 and Lemma 1.3 by using the monotonicity of the frequency function [7]. Such a method is limited to elliptic equations of the second order. Later on, we proved Lemma 1.2 and Lemma 1.3 by using the singular integrals. In fact, we proved these results for elliptic equations of the arbitrary order. For details, see [10].

Now we state the main result in this section. It is taken from [9].

**Theorem 1.4.** Let $u$ be a $C^2$ solution to (0.1) with (0.2) and (0.3). Then there exists the following decomposition

$$S(u) = \bigcup_{j=0}^{n-2} S^j(u),$$

where each $S^j(u)$ is on a countable union of $j$-dimensional $C^1$ graphs, $j = 0, 1, \cdots, n - 2$.

**Proof.** The proof consists of several steps. For each fixed $d \geq 2$, we shall study
$$S_d(u) = \{p \in S(u); O(u) = d\}.$$

**Step 1.** We use Lemma 1.2 to study the local behavior at each point.

For each point $y \in B_2 \cap S_d(u)$, set for any $r \in (0, \frac{1-|y|}{2})$,

$$u_{y,r}(x) = \frac{u(y + rx)}{(\int_{\partial B_r(y)} |u|^2)^{\frac{1}{2}}} \text{ for any } x \in B_2.$$  \hfill (1.3)

Then by Lemma 1.2, we have

$$u_{y,r} \to P \text{ in } L^2(B_2) \text{ as } r \to 0,$$

where $P = P_y$ is a $d$-degree non-zero homogeneous polynomial satisfying

$$\sum_{i,j=1}^{n} a_{ij}(0) \partial_{ij} P = 0.$$ \hfill (1.5)

Moreover, $\|P\|_{L^2(\partial B_1)} = 1$. Note $P$ is the normalized leading polynomial of $u$ at $y$.

Since $P$ is a $d$-degree non-zero homogeneous polynomial, we have

$$S_d(P) = \{x; \partial^\nu P(x) = 0, \text{ for any } |\nu| \leq d - 1\}.$$
SINGULAR SETS

Obviously $0 \in S_d(P)$ by the homogeneity of $P$. It is easy to see that $S_d(P)$ is a linear subspace and

$$(1.6) \quad P(x) = P(x + z) \quad \text{for any } x \in \mathbb{R}^n \text{ and } z \in S_d(P).$$

Next, we observe that $\dim S_d(P) \leq n - 2$ for $d \geq 2$. In fact, (1.6) implies $P$ is a function of $n - \dim S_d(P)$ variables. If $\dim S_d(P) = n - 1$, $P$ would be a $d$-degree monomial of one variable satisfying the equation (1.5). Hence $d < 2$.

**Step 2.** We define for each $j = 0, 1, 2, \ldots, n - 2$,

$$S_d^j(u) = \{y \in S_d(u) ; \dim S_d(P_y) = j\}.$$

We claim that $S_d^j(u)$ is on a countable union of $j$-dimensional $C^1$ graphs. In fact, we shall prove that for any $y \in S_d^j(u)$ there exists an $r = r(y)$ such that $S_d^j(u) \cap B_r(y)$ is contained in a (single piece of) $j$-dimensional $C^1$ graph.

To show this, we let $\ell_y$ be the $j$-dimensional linear subspace $S_d(P_y)$ for any $y \in S_d^j(u)$. For any $\{y_k\} \subset S_d^j(u)$ with $y_k \to y$, we first prove

$$(1.7) \quad \text{Angle } < \frac{yy_k}{\ell_y}, \ell_y > \to 0.$$  

To prove (1.7), we may assume $y = 0$ and $p_k = \frac{y_k}{|y_k|} \to \xi \in \mathbb{S}^{n-1}$. Note $p_k \in S_d(u_0, |y_k|)$ for

$$u_0,|y_k|(x) = \frac{u(|y_k|x)}{\left( \int_{\partial B_{|y_k|} (0)} u^2 \right)^{1/2}}.$$  

See (1.3) for notations. We may show by an elementary calculation that

$$\mathcal{L}_k u_0,|y_k| = 0,$$

where $\mathcal{L}_k$ is some second order elliptic operator with a similar structure as $\mathcal{L}$. Moreover, for $\mathcal{L}$ as in (0.1), we have

$$\mathcal{L}_k \to \mathcal{L}_0 \equiv \sum_{i,j=1}^{n} a_{ij}(0) \partial_{ij},$$

in the sense that corresponding coefficients converge uniformly. Then by applying Lemma 1.3, we obtain that $P_y$ vanishes at $\xi$ with an order at least $d$, i.e.,

$$O_{P_y}(\xi) \geq d.$$  

Since $P_y$ is a $d$-degree homogeneous polynomial, then $O_{P_y}(\xi) = d$ and $\xi \in \ell_y$. This implies (1.7).

By (1.7), we obtain that for any $y \in S_d^j(u)$ and small $\varepsilon > 0$ there exists an $r = r(y, \varepsilon)$ such that

$$(1.8) \quad S_d^j(u) \cap B_r(y) \subset B_r(y) \cap C_\varepsilon(\ell_y),$$

where

$$C_\varepsilon(\ell_y) = \{z \in \mathbb{R}^n ; \text{dist}(z, \ell_y) \leq \varepsilon |z| \}. $$
Let $P_k$ and $P$ be leading polynomials of $u$ at $y_k$ and $y = 0$, respectively. By Lemma 1.3, we have

$$P_k \rightarrow P \quad \text{uniformly in } C^d(B_1).$$

This implies

$$\ell_{y_k} \rightarrow \ell_y \quad \text{as } k \rightarrow \infty,$$

as subspaces in $\mathbb{R}^n$. By an argument similar as proving (1.7), we may prove that the constant $r$ in (1.8) can be chosen uniformly for any point $z \in L^j_d(u)$ in a neighborhood of $y$. In other words, for any $y \in S^j_d(u)$ and any small $\varepsilon > 0$ there exists an $r = r(\varepsilon, y)$ such that

$$S^j_d(u) \cap B_r(z) \subset B_r(z) \cap C_\varepsilon(\ell_z) \quad \text{for any } z \in S^j_d(u) \cap B_r(y).$$

For $\varepsilon > 0$ small enough, this clearly implies that $S^j_d(u) \cap B_r(y)$ is contained in a $j$-dimensional Lipschitz graph. By (1.7) this graph is $C^1$.

**Remark 1.5.** In fact, we can prove $S^{n-2}(u)$ is on a countable union of $(n-2)$-dimensional $C^{1,\beta}$ manifolds, for some $0 < \beta < 1$.

Now we write a corollary of Theorem 1.4.

**Corollary 1.6.** Let $u$ be a solution as in Theorem 1.4. Then there holds

$$S(u) = S^*(u) \cap S^*(u),$$

where the Hausdorff dimension of $S^*(u)$ is at most $n - 3$, and for any $p \in S^*(u)$ the leading polynomial of $u$ at $p$ is a polynomial of two variables after some rotation of coordinates.

To conclude the present section, we illustrate by an example that in $\mathbb{R}^3$ the singular set can be any closed subset in a line segment.

### 2. The Measure of Singular Sets

In this section, we shall discuss the geometric measure of singular sets.

We begin with a simple example. Consider a homogenous harmonic polynomial of degree $d$ in $\mathbb{R}^2$. By using the polar coordinate $x_1 = r \cos \theta$ and $x_2 = r \sin \theta$ in $\mathbb{R}^2 = \{(x_1, x_2)\}$, we may assume $P(x) = r^d \cos d \theta$. A direct calculation shows that

$$\partial_1 P = dr^{d-1} \cos(d-1) \theta, \quad \partial_2 P = -dr^{d-1} \sin(d-1) \theta.$$

Therefore both $\partial_1 P$ and $\partial_2 P$ are products of $d - 1$ different homogeneous linear functions. Now assume $u$ is a smooth perturbation of $P$ in $B_1$. Then it is not hard to imagine that the critical set of $u$ has at most $(d-1)^2$ points in $B_1$. As we shall see, this is quite difficult to prove.

This simple observation illustrates that the size of singular sets of harmonic polynomials depend on the degree. In order to obtain a measure estimate of singular sets of solutions to general elliptic equations, we first need to introduce a quantity to measure the growth of solutions.
SINGULAR SETS

Suppose that $\mathcal{L}$ is an elliptic operator of the form (0.1) satisfying (0.2) and (0.3) and that $u$ is a $C^2$ solution of $\mathcal{L}u = 0$ in $B_1$. Set

\[
(2.1) \quad N = \frac{\int_{B_1} |\partial u|^2}{\int_{\partial B_1} u^2}.
\]

It is proved in [7] that $u$ satisfies

\[
\int_{B_{2r}(p)} u^2(x) dx \leq 4^{c_0 N} \int_{B_r(x_0)} u^2(x) dx,
\]

for any $x_0 \in B_{1/2}$, $r < r_0$, where $c_0$ and $r_0 < 1/3$ are positive constants depending only on $\lambda, \kappa, K$ and $n$. Here, we denote

\[
\int_{B_{\rho}(x_0)} u^2(x) dx \equiv \rho^{-n} \int_{B_{\rho}(x_0)} u^2(x) dx.
\]

We then conclude that the vanishing order of $u$ at any point $p \in B_{1/2}$ does not exceed $c_0 N$.

The quantity $N$ in (2.1) is called the frequency of $u$ in $B_1$. It controls the vanishing order of $u$. If $u$ is a homogeneous harmonic polynomial, the frequency is exactly the degree. See [7] for a discussion of the frequency and related topics. In [16], Lin conjectured that

\[
\mathcal{H}^{n-2}(S(u) \cap B_{1/2}) \leq cN^2,
\]

where $c$ is a positive constant depending only on the elliptic operator $\mathcal{L}$.

The main result is the following theorem. It is taken from [12].

**Theorem 2.1.** Suppose that $\mathcal{L}$ is an elliptic operator of the form (0.1) satisfying (0.2) and (0.3) and that $u$ is a $C^2$ solution of $\mathcal{L}u = 0$ in $B_1$ with

\[
\frac{\int_{B_1} |\partial u|^2}{\int_{\partial B_1} u^2} \leq N_0,
\]

for some positive constant $N_0$. Then there exists a positive integer $M$, depending on $N_0, \lambda, \kappa$ and $K$, such that if, in addition, $a_{ij}, b_i, c \in C^M(B_1)$, there holds

\[
\mathcal{H}^{n-2}(S(u) \cap B_{1/2}) \leq C,
\]

where $C$ is a positive constant depending on $N_0, \lambda, \kappa, K$ and the $C^M$-norms of the coefficients $a_{ij}, b_i$ and $c$.

The key result is the following lemma for functions in $\mathbb{R}^2$.

**Lemma 2.2.** Let $P$ be a homogeneous harmonic polynomial of degree $d \geq 2$ in $\mathbb{R}^2$. Then there exist positive constants $\delta$ and $\tau$, depending on $P$, such that for any $u \in C^{2d^2}(B_1)$ with

\[
|u - P|_{C^{2d^2}(B_1)} < \delta,
\]

there holds

\[
\#(|Du|^{-1} \{0\} \cap B_{1/2}) \leq c(d - 1)^2,
\]
where $c$ is a universal constant.

The proof of Lemma 2.2 is based on the Weierstrass-Malgrange Preparation Theorem for finitely differentiable functions. See [12] for details.

Now we describe the proof of Theorem 2.1.

**Proof of Theorem 2.1.** The proof consists of several steps.

**Step 1.** Set

$S_*(u) = \{ p \in S(u) ; \text{ the leading polynomial of } u \text{ at } p \text{ is a polynomial of two variables by an appropriate rotation} \}$.

By Corollary 1.6, we have

$$\mathcal{H}^{n-2}(S(u) \setminus S_*(u)) = 0.$$  

Then for any $\varepsilon > 0$, there exist at most countably many balls $B_{r_i}(x_i)$ with $r_i \leq \varepsilon$ and $x_i \in S(u) \setminus S_*(u)$ such that

$$S(u) \setminus S_*(u) \subset \bigcup_i B_{r_i}(x_i),$$

and

$$\sum r_i^{n-2} \leq \gamma(\varepsilon, u),$$

where $\gamma(\varepsilon, u) \rightarrow 0$ as $\varepsilon \rightarrow 0$.

We claim for any $y \in S_*(u) \cap B_{3/4}$, there exist $R = R(y, u), r = r(y, u)$ and $c = c(y, u)$, with $r < R$, such

$$\mathcal{H}^{n-2} \{ B_r(y) \cap S(u) \} \leq cr^{n-2}.$$  

The proof of (2.4) is based on Lemma 2.2 and the fact that the degree of the leading polynomial at any $p \in S_*(u)$ is at most $c_0 N$. We omit the details.

It is obvious that the collection of $\{B_{r_i}(x_i)\}$ and $\{B_r(y)\}, y \in S_*(u)$, covers $S(u)$. By the compactness of $S(u)$, there exist $x_i \in S(u) \setminus S_*(u), i = 1, \cdots, k = k(\varepsilon, u)$, and $y_j \in S_*(u), j = 1, \cdots, l = l(\varepsilon, u)$, such that

$$S(u) \cap B_{3/4} \subset \left( \bigcup_{i=1}^k B_{r_i}(x_i) \right) \bigcup \left( \bigcup_{j=1}^l B_{s_j}(y_j) \right),$$

with $r_i \leq \varepsilon, i = 1, \cdots, k,$ and $s_j \leq \varepsilon, j = 1, \cdots, l$.

**Step 2.** In Step 1, The constant $\gamma$ in (2.3) and $c$ in (2.4) depend on $u$. To improve the results established in Step 1, we should work in a compact class of elliptic operators satisfying (0.1)-(0.3) and in a compact class of solutions with controlled frequency. Then by a compactness argument, we conclude the following result. Let $u$ be as given in Theorem 2.1. For any $\varepsilon > 0$ there exist positive constants $C(\varepsilon)$ and $\gamma(\varepsilon)$, depending also on $N_0$, as well as $\lambda, \kappa, K$ and $n$, with $\gamma(\varepsilon) \rightarrow 0$ as $\varepsilon \rightarrow 0$, such that there exists a collection of balls $\{B_{r_i}(x_i)\}$ with $r_i \leq \varepsilon$ and $x_i \in S(u)$ such that

$$\mathcal{H}^{n-2} (S(u) \cap B_{1/2} \setminus \cup B_{r_i}(x_i)) \leq C(\varepsilon),$$

$\mathcal{H}^{n-2}$
SINGULAR SETS

and

$$\sum r_i^{n-2} \leq \gamma(\epsilon).$$

We emphasize that $C(\epsilon)$ and $\gamma(\epsilon)$ are independent of $u$.

Step 3. We use the standard iteration process to prove Theorem 2.1. To begin with, define

$$\phi_0 = \{B_{1/2}(0)\}.$$

Fix an $\epsilon > 0$. We claim that we may find $\phi_1, \phi_2, \ldots$, each of which consists of a collection of balls, such that for any $\ell \geq 1$

$$\text{rad}(B) \leq \frac{(2\epsilon)^\ell}{2} \quad \text{for any } B \in \phi_\ell,$$

$$\sum_{B \in \phi_\ell} \text{rad}(B)]^{n-2} \leq \gamma(\epsilon)^\ell,$$

and

$$\mathcal{H}^{n-2} \left( S(u) \cap \bigcup_{B \in \phi_{\ell-1}} B \setminus \bigcup_{B \in \phi_\ell} B \right) \leq C(\epsilon)[\gamma(\epsilon)]^{\ell-1},$$

where $C(\epsilon)$ and $\gamma(\epsilon)$ are given in Step 2. Observe that

$$S(u) \cap B_{1/2}(0) \subset \bigcup_{\ell=1}^\infty \left( S(u) \cap \left( \bigcup_{B \in \phi_{\ell-1}} B \setminus \bigcup_{B \in \phi_\ell} B \right) \right) \cup \bigcap_{\ell=0}^\infty \left( S(u) \cap \bigcup_{j=\ell}^\infty \bigcup_{B \in \phi_j} B \right).$$

Hence we have

$$\mathcal{H}^{n-2} (S(u) \cap B_{1/2}(0)) \leq C(\epsilon) \left\{ \sum_{\ell \geq 1} [\gamma(\epsilon)]^{\ell-1} + \inf_{\ell \geq 1} \sum_{j=\ell}^\infty [\gamma(\epsilon)]^j \right\}$$

$$\leq 2C(\epsilon),$$

provided we take $\epsilon$ small such that $\gamma(\epsilon) \leq 1/2$.

To prove the claim we construct $\{\phi_\ell\}$ by an induction. Note $\phi_0 = \{B_{1/2}\}$, independent of $\epsilon$. Suppose $\phi_0, \phi_1, \ldots, \phi_{\ell-1}$ are already defined for some $\ell \geq 1$. To construct $\phi_\ell$, we take $B = B_r(y) \in \phi_{\ell-1}$, with $r \leq 1/2$. Consider the transformation $x \mapsto y + 2rx$. Then, via $Lu = 0$ in $B_{2r}(y)$, we have

$$\tilde{L}\tilde{u} = 0 \quad \text{in} \quad B_1(0),$$

where

$$\tilde{L} = \sum_{i,j=1}^n a_{ij}(y + 2rx)\partial_{x_i x_j} + \sum_{i=1}^n 2rb_i(y + 2rx)\partial_{x_i} + (2r)^2c(y + 2rx),$$

and

$$\tilde{u}(x) = u(y + 2rx).$$
Note Step 2 can be applied to $\tilde{L}$ and $\tilde{\mu}$. Hence we obtain a collection of balls $\{B_{s_{i}}(z_{i})\}$ with $s_{i} \leq \varepsilon$ and $z_{i} \in S(\tilde{\mu})$ such that
\[
H^{n-2}(S(\tilde{\mu}) \cap B_{1/2} \setminus \cup B_{s_{i}}(z_{i})) \leq C(\varepsilon),
\]
and
\[
\sum s_{i}^{n-2} \leq \gamma(\varepsilon).
\]
Now transform $B_{1/2}$ back to $B_{r}(y)$ by $x \mapsto (x - y)/2r$. We obtain that for $B = B_{r}(y) \in \phi_{\ell-1}$, there exist finitely many balls $\{B_{r_{i}}(x_{i})\}$ in $B_{2r}(y)$, with $r_{i} \leq 2\varepsilon r$, such that
\[
H^{n-2}\left(S(u) \cap B_{r}(y) \setminus \bigcup_{i} B_{r_{i}}(x_{i})\right) \leq C(\varepsilon)r^{n-2},
\]
and
\[
\sum r_{i}^{n-2} \leq r^{n-2}\gamma(\varepsilon).
\]
Then we set
\[
\phi_{B}^{\ell} = \bigcup_{i} B_{i}(x_{i}),
\]
and
\[
\phi_{\ell} = \bigcup_{B \in \phi_{\ell-1}} \phi_{B}^{\ell}.
\]
Hence we obtain
\[
H^{n-2}\left(S(u) \cap \bigcup_{B \in \phi_{\ell-1}} B \setminus \bigcup_{B \in \phi_{\ell}} B\right) \leq C(\varepsilon) \left(\sum_{B_{r_{i}}(x_{i}) \in \phi_{\ell-1}} r_{i}^{n-2}\right),
\]
and by an induction
\[
r_{i} \leq \frac{(2\varepsilon)^{\ell}}{2}, \quad \sum_{B_{r_{i}}(x_{i}) \in \phi_{\ell}} r_{i}^{n-2} \leq [\gamma(\varepsilon)]^{\ell},
\]
for each $\ell \geq 1$. This concludes the proof. \hfill \square

3. COMPLEX SINGULAR POINTS OF PLANAR HARMONIC FUNCTIONS

In the previous section, we derived a uniform estimate in terms of the frequency for the measure of singular sets to homogenous elliptic equation. Up to now, no explicit estimates are known even for harmonic functions. In this section, we shall derive an explicit estimate for planar harmonic functions.

Suppose $u$ is a harmonic function defined in the unit ball in $\mathbb{R}^{2}$. Then $u$ can be extended to a holomorphic function in some ball in $\mathbb{C}^{2}$. To see this, we simply consider the Taylor expansion of $u = u(x)$ at the origin and replace $x \in \mathbb{R}^{2}$ by $z \in \mathbb{C}^{2}$. With the estimate of the derivatives of harmonic functions, the new complex series converges for $|z| < R$, with $R \in (0,1)$ to be a universal constant. In the following, we always denote by $\tilde{u}$ the
SINGULAR SETS

complexification of $u$. We shall also use $B_r(x)$ and $D_r(z)$ to denote open balls of radius $r$ centered at $x$ and $z$ in $\mathbb{R}^2$ and $\mathbb{C}^2$, respectively. When the center is the origin, we will simply write $B_r$ and $D_r$. The singular sets of $u$ and $\tilde{u}$ are defined as

\[ S(u) = \{x \in B_1; u(x) = \partial_{x_1}u(x) = \partial_{x_2}u(x) = 0\}, \]
\[ S(\tilde{u}) = \{z \in D_{R_0}; \tilde{u}(z) = \partial_{z_1}\tilde{u}(z) = \partial_{z_2}\tilde{u}(z) = 0\}. \]

The main result in this section is the following theorem from [11].

**Theorem 3.1.** Let $u$ be a (real) harmonic function in $B_1 \subset \mathbb{R}^2$. Then for some universal constants $R_0 \in (0, 1)$ and $c > 0$ there holds

\[ \# (S(\tilde{u}) \cap D_{R_0}) \leq cN^2, \]

where $N$ is defined as in (2.1).

A significant aspect of Theorem 3.1 is that a property of the complexified $\tilde{u}$ is determined by its restriction on the real space $u = \tilde{u}|_{\mathbb{R}^2}$. Here we make an important remark about the complexification $\tilde{u}$. Since $u$ is a harmonic function, the holomorphic function $\tilde{u}$ satisfies

\[ \partial_{z_1z_1}\tilde{u} + \partial_{z_2z_2}\tilde{u} = 0. \]

Theorem 3.1 asserts that the singular set of $\tilde{u}$ is isolated and that the number of singular points can be estimated in terms of the frequency of the (real) function $u$. This result does not hold for general holomorphic functions $v$ satisfying

\[ \partial_{z_1z_1}v + \partial_{z_2z_2}v = 0. \]

(3.1)

The following example is taken from [14].

**Example 3.2.** Let $v(z) = (z_1 - iz_2)^2$. Obviously $v$ satisfies (3.1). However, the singular set of $v$ is not even isolated.

Hence in order to have an isolated singular set for a holomorphic function $v = v(z_1, z_2)$ satisfying (3.1), all the coefficients in the Taylor expansion of $v$ have to be real.

Now we begin to prove Theorem 3.1.

We first consider the gradient of homogeneous harmonic polynomials. We identify $\mathbb{R}^2 = \mathbb{C}$ and use the complex coordinate $z = x_1 + ix_2$. Consider the homogeneous polynomial

\[ \bar{z}^d = (x_1 - ix_2)^d = r^d \cos d\theta - ir^d \sin d\theta. \]

We use its real part and complex part to construct a homogeneous polynomial map $Q_d : \mathbb{R}^2 \to \mathbb{R}^2$ as follows

\[ Q_d(x) = Q_d(x_1, x_2) = \begin{pmatrix} r^d \cos d\theta \\ -r^d \sin d\theta \end{pmatrix} = \begin{pmatrix} \frac{1}{2}(z^d + \bar{z}^d) \\ \frac{1}{2}(z^d - \bar{z}^d) \end{pmatrix}, \]
Each component is a homogeneous harmonic polynomial. In fact $Q_d$ is the gradient of some homogeneous harmonic polynomial of degree $d + 1$. Now we extend the map $Q_d : \mathbb{C}^2 \to \mathbb{C}^2$ simply by replacing $x = (x_1, x_2)$ by $z = (z_1, z_2)$,

$$Q_d(z) = Q_d(z_1, z_2) = \left(\frac{1}{2}((z_1 + iz_2)^d + (z_1 - iz_2)^d), \frac{1}{2}((z_1 + iz_2)^d - (z_1 - iz_2)^d)\right).$$

We conclude easily

$$|Q_d(z)|^2 = \frac{1}{2}(|z_1 + iz_2|^{2d} + |z_1 - iz_2|^{2d}) = \frac{1}{2} \left((|z_1|^2 + |z_2|^2 + 2(y_1x_2 - x_1y_2))^d + (|z_1|^2 + |z_2|^2 - 2(y_1x_2 - x_1y_2))^d\right).$$

Notice that only the even power of $y_1x_2 - x_1y_2$ appears in the right side. Hence we get

$$|Q_d(z)| \geq |z|^d.$$
SINGULAR SETS

Next, we list some well known properties of harmonic functions. Suppose $u$ is a harmonic function in $B_1 \subset \mathbb{R}^2$. For any $p \in B_1$, the frequency function $N(p, \cdot)$ at $p$ is defined as

$$N(p, r) = \frac{r \int_{B_r(p)} |\nabla u|^2}{\int_{\partial B_r(p)} u^2}.$$  

The frequency $N$ in (2.1) is in fact $N(0, 1)$.

The following result is exactly Theorem 1.1 in [16].

**Theorem 3.5.** $N(p, r)$ is a monotone nondecreasing function of $r \in (0, 1 - |p|)$ for any $p \in B_1$.

A corollary of this monotonicity is the doubling property, which we state only for $p = 0$. There holds for any $r \in (0, 1/2)$,

$$\frac{1}{2r} \int_{\partial B_{2r}} u^2 \leq 2^{2N(0, 1)} \frac{1}{r} \int_{\partial B_r} u^2. $$

In fact, there holds a more general result for $0 < r_1 < r_2 \leq 1$

(3.5)  

$$\frac{1}{r_2} \int_{\partial B_{r_2}} u^2 \leq \left( \frac{r_2}{r_1} \right)^{2N(0, 1)} \frac{1}{r_1} \int_{\partial B_{r_1}} u^2. $$

For details, see [16].

We also need the following corollary of Theorem 3.5.

**Corollary 3.6.** There exists a universal constant $N_0 \ll 1$ such that the following holds. If $N(0, 1) \leq N_0$, then $u$ does not vanish in $B_{1/2}$. If $N(0, 1) \geq N_0$, then there holds

$$N(p, \frac{1}{4}) \leq C N(0, 1), \quad \text{for any } p \in B_{\frac{1}{2}},$$

where $C$ is a universal constant.

The proof follows exactly the same argument in the proof of Proposition 1.2 in [16] and is skipped. In fact, both assertions are proved there explicitly.

The second property we need is the complexification. Again, suppose $u$ is a harmonic function in $B_1 \subset \mathbb{R}^2$. Then for some universal $R \in (0, 1)$, $u$ extends to a holomorphic function $\tilde{u}(z)$ in $D_R \subset \mathbb{C}^2$. Moreover, there holds for some universal constant $c > 0$

(3.6)  

$$\sup_{D_R} |\tilde{u}| \leq c \|u\|_{L^2(\partial B_1)}.$$

In the following, $R$ will be fixed such that the above extension property and (3.6) hold. Hence, the constant $c$ is also fixed, independent of $u$.

Now we begin to prove Theorem 3.1. We shall prove the following result. The constant $N$ in Theorem 3.7 means different from that in (2.1).
Theorem 3.7. There are two universal constants $M > 1$ and $r \in (0, 1)$ such that for a harmonic function $u$ in $B_M \subset \mathbb{R}^2$, with $u(0) = 0$, satisfying
\[
\frac{M \int_{B_M} |\nabla u|^2}{\int_{\partial B_M} u^2} \leq N,
\]
there holds
\[
\# \{z \in D_r; \tilde{u}_{z_1}(z) = \tilde{u}_{z_2}(z) = 0\} \leq 4N^2.
\]
Proof. For simplicity, we shall use the same notation to denote harmonic functions and their complexifications. Let $(r, \theta)$ denote polar coordinates in $\mathbb{R}^2$ and we write $u$ in the following form
\[
u(r, \theta) = \sum_{m=1}^{\infty} a_m \Phi_m(r, \theta), \quad \text{and} \quad \Phi_m(r, \theta) = r^m \varphi_m(\theta),
\]
where $\varphi_m(\theta)$ satisfies
\[
\int_{S^1} \varphi_m^2(\theta) d\theta = 1, \quad \text{and} \quad \varphi_m''(\theta) + m^2 \varphi_m(\theta) = 0.
\]
Moreover, we may assume, without loss of generality, that
\[
(3.7) \quad \int_{\partial B_1} u^2 = \sum_{m=1}^{\infty} a_m^2 = 1.
\]
In the following, we set
\[
N_* = \inf \{n \in \mathbb{Z}_+; n \geq N\}.
\]
In other words, $N_* = N$ if $N$ is an integer and $N_* = [N] + 1$ otherwise. Here $[N]$ is the integral part of $N$. Obviously, we have
\[
N_* - 1 \leq N \leq N_*.
\]
By (3.5), we get
\[
\frac{1}{M} \int_{\partial B_M} u^2 \leq M^{2N(0,M)} \int_{\partial B_1} u^2 = M^{2N(0,M)},
\]
which implies
\[
\sum_{m=1}^{\infty} a_m^2 M^{2m} \leq M^{2N(0,M)}.
\]
By $N(0,M) \leq N \leq N_*$, we have obviously
\[
\sum_{m=1}^{\infty} a_m^2 M^{2m} \leq M^{2N_*}.
\]
Therefore, we obtain
\[
(3.8) \quad |a_m| \leq M^{N_* - m}, \quad \text{for any } m \geq 1.
\]
SINGULAR SETS

Since \( \{ \varphi_m \} \) is orthonormal in \( L^2(S^1) \), there holds for some universal constant \( c > 0 \)
\[
\int_{B_1} | \sum_{m \geq 2N_*} a_m \Phi_m |^2 = \sum_{m \geq 2N_*} |a_m|^2 \leq \frac{c}{M^{2N_*}}.
\]
We first choose \( M \) large, independent of \( N_* \), such that
\[
(3.9) \quad \sum_{m \geq 2N_*} \infty |a_m|^2 \leq \frac{1}{2}.
\]
By (3.6), we get for some universal \( R \in (0,1) \),
\[
\sup_{D_R} | \sum_{m \geq 2N_*} a_m \Phi_m | \leq \frac{c}{M N_*}. 
\]
Interior estimates for holomorphic functions imply
\[
(3.10) \quad \sup_{D_{R/2}} | \partial ( \sum_{m \geq 2N_*} a_m \Phi_m ) | \leq \frac{c}{R M N_*}.
\]
Set
\[
(3.11) \quad P_* = \sum_{m=1}^{2N_*-1} a_m \Phi_m, \quad R_* = \sum_{m \geq 2N_*} \infty a_m \Phi_m.
\]
Then \( u = P_* + R_* \). Obviously, we have by (3.7) and (3.9)
\[
\sum_{m=1}^{2N_*-1} |a_m|^2 \geq \frac{1}{2}.
\]
Then \( \partial P_* \) satisfies the assumptions in Lemma 3.3, with \( d = 2N_* - 2 \) and possibly a different normalization constant. By choosing \( M \) large enough, independent of \( N_* \), we conclude by (3.10)
\[
\sup_{D_{R/2}} |D R_* | < \epsilon^{2N_*-2},
\]
where \( \epsilon \) is the universal constant as in Corollary 3.4, or Lemma 3.3. This implies
\[
|\partial u(z) - \partial P_*(z) | < \epsilon^{2N_*-2}, \quad \text{for any } z \in D_{R/2}.
\]
By applying Corollary 3.4 to \( \partial u \) in \( D_{R/2} \), we conclude that
\[
\# \{ |\partial u|^{-1}(0) \cap D_{R/4} \} \leq (2N_* - 2)^2.
\]
This finishes the proof, since \( N_* - 1 \leq N \).
\[\square\]

Now we may prove Theorem 3.1.

Proof of Theorem 3.1. Recall \( N \) is defined in (2.1).

First, we consider the case that \( N \) is small. Let \( N_0 \) be the constant in Corollary 3.6. If \( N \leq N_0 \), then \( u \) is never zero in \( B_{1/4} \) by Corollary 3.6. Harnack inequality and interior estimates for harmonic functions and
HAN

holomorphic functions imply that $u$ has no zeroes in $D_{R_1}$, for some universal $R_1 < 1$. Therefore we have $S(u) \cap D_{R_1} = \phi$.

Next, we consider $N \geq N_0$. By Corollary 3.6, there holds for any $p \in B_{1/4}$

$$\frac{\int_{B_{1/4}(p)} |\nabla u|^2}{4 \int_{\partial B_{1/4}(p)} u^2} \leq CN,$$

for some positive constant $C$ independent of $u$. For any $p \in B_{1/4}$, with $u(p) = 0$, by the scaled version of Theorem 3.7, we have

$$\#\{S(u) \cap D_{R_2}(p)\} \leq cN^2,$$

for some positive constants $R_2 < 1$ and $c$, independent of $u$ and $p$. To finish the proof, we consider two cases. If $u$ is never zero in $B_{R_2/2}$, then $u$ is never zero in $D_{2R_1R_2}$, as in the first part of the proof. This implies that $S(u) \cap D_{2R_1R_2} = \phi$. If $u(p) = 0$ for some $p \in B_{R_2/2}$, then we have

$$\#\{S(u) \cap D_{R_2}(p)\} \leq cN^2,$$

which implies

$$\#\{S(u) \cap D_{R_2/2}\} \leq cN^2.$$

This finishes the proof by taking $R_0 = \min\{R_1, 2R_1R_2, R_2/2\}$. 

To finish this section, we give an example to show that the number of complex singular points is indeed in the quadratic order of the frequency. Hence the estimate in Theorem 3.1 is optimal.

**Example 3.8.** For any integer $d \geq 2$ and any small $\varepsilon > 0$, consider the harmonic polynomial $u$ in the polar coordinate

$$u(x) = \varepsilon r \cos \theta - \frac{1}{d+1} r^{d+1} \cos(d + 1) \theta.$$

Then it is easy to see that

$$\partial u(x) = \begin{pmatrix} \varepsilon - r^d \cos d\theta \\ r^d \sin d\theta \end{pmatrix}.$$ 

By (3.3), we have

$$\partial \tilde{u}(z) = \begin{pmatrix} \varepsilon - \frac{1}{2} \left((z_1 + i z_2)^d + (z_1 - i z_2)^d\right) \\ -\frac{1}{2} \left((z_1 + i z_2)^d - (z_1 - i z_2)^d\right) \end{pmatrix}.$$ 

A simple calculation shows that $D\tilde{u}(z) = 0$ has $d^2$ solutions close to the origin. Obviously, the frequency of $u$ is in the order of $d$.
