THE MICROLOCAL SMOOTHING EFFECT FOR SCHRÖDINGER TYPE OPERATORS IN GEVREY CLASSES

KUNIHKO KAJITANI & GIOVANNI TAGLIALATELA (Un. Tsukuba)

Let $T > 0$, we consider the Cauchy problem,

$$
\begin{cases}
Lu = 0, & t \in [-T, T], \ x \in \mathbb{R}^n, \\
u(0, x) = u_0(x), & x \in \mathbb{R}^n,
\end{cases}
$$

where

$$
Lu = \partial_t u - \sqrt{-1} \sum_{j,k=1}^{n} \frac{\partial}{\partial x_j} (a_{jk}(x) \frac{\partial}{\partial x_k} u) - \sum_{j=1}^{||} b_j(t, x) \frac{\partial}{\partial x_j} u - b_0(t, x) u,
$$

$$a_2(x, \xi) = \sum_{j,k=1}^{n} a_{jk}(x) \xi_j \xi_k,$$

is a real elliptic symbol with smooth and bounded coefficients.

We will consider the smoothing effect phenomenon: more the initial data decays at the infinity, more the solution of (1) is regular. In the case of microlocal smoothing effect, the decay of initial data is required only on a neighborhood of the backward bicharacteristic.

Recall that a function $f$ belongs to the Gevrey class $\gamma^d(\Omega)$, if $f \in \mathcal{C}^\infty(\Omega)$ and for any compact $K$ of $\Omega$ there exist positive constants $\rho$ and $C$ such that

$$
\sup_{x \in K} |D^\alpha f(x)| \leq C \rho^{-|\alpha|} |\alpha|^d,
$$

for all $\alpha \in \mathbb{N}^n$.

A point $(y_0, \eta_0) \in T^*\mathbb{R}^n$ does not belong to the Gevrey wave front set of order $d$ of a distribution $u$ if there exists a function $\chi \in \gamma^d(\mathbb{R}^n)$ ($= \gamma^d(\mathbb{R}^n) \cap \mathcal{C}_0^\infty(\mathbb{R}^n)$), equal to 1 in a neighborhood of 0, such that if one sets $\chi_{y_0}(x) = \chi(x - y_0)$ and $\chi_{\eta_0}(\xi) = \left(\xi \over |\xi| - \eta_0 \over |\eta_0|\right)$, then there exist positive constants $C$ and $\rho$ such that

$$
|D^\alpha_x \left(\chi_{\eta_0}(D)(\chi_{y_0}(x)u)\right)| \leq C \rho^{-|\alpha|} |\alpha|^d,
$$

for all $\alpha \in \mathbb{N}^n$. We will note $WF_d u$ the wave front set of order $d$ of $u$.

Assumption I.

1. $a_{jk} \in \gamma^d(\mathbb{R}^n)$, for some $d \geq 1$;
2. there exists a positive constant $C$ such that

$$
C^{-1} |\xi|^2 \leq a_2(x, \xi) \leq C |\xi|^2,
$$

for all $\xi \in \mathbb{R}^n$;
3. there exist positive constants $\delta$, $\rho$ and $C$ such that

$$
|D^\alpha_x a_{jk}(x)| \leq C \rho^{-|\alpha|} |\alpha|^d (x)^{-|\alpha|-\delta},
$$
for all $x \in \mathbb{R}^n$, $\alpha \in \mathbb{N}^n \setminus \{0\}$, for all $j, k = 1, \ldots, n$;
4. there exists $\theta(x, \xi) \in \gamma^d(\mathbb{R}^n \times \mathbb{R}^n)$ such that
   (a) there exist positive constants $\rho$ and $C$ such that
       \[ |D_x^\alpha D_\xi^\beta \theta(x, \xi)| \leq C \rho^{-|\alpha|} |\alpha|! |\beta|!^{d} \langle \xi \rangle^{1-|\alpha|} \langle x \rangle^{1-|\beta|}, \]
       for all $x, \xi \in \mathbb{R}^n$, $\alpha, \beta \in \mathbb{N}^n$;
   (b) $H_a \theta(x, \xi) \geq C |\xi|^2$, for some positive constant $C$, where $H_a$ is the Hamiltonian flow associated to $a_2: H_a = \sum_{j=1}^n \frac{\partial a_2}{\partial \xi_j} \frac{\partial}{\partial x_j} - \frac{\partial a_2}{\partial x_j} \frac{\partial}{\partial \xi_j}$.

Assumption II.
1. $b_j \in C([0, T]; \gamma^d(\mathbb{R}^n))$, for $j = 0, 1, \ldots, n$ and there exist positive constants $\rho$ and $C$ such that
   \[ |D_\xi^\alpha b_j(t, x)| \leq C \rho^{-|\alpha|} |\alpha|! \langle x \rangle^{-|\alpha|}, \]
   for all $x \in \mathbb{R}^n$, $\alpha \in \mathbb{N}^n \setminus \{0\}$, for all $j = 0, 1, \ldots, n$;
2. $\text{Im } b_j(t, x) = 0$, for $j = 1, \ldots, n$.

For $(y_0, \eta_0) \in T^*\mathbb{R}^n$, we consider the bicharacteristic of $a_2(x, \xi)$ passing through $(y_0, \eta_0)$:
\[
\begin{cases}
\dot{X}(s) = \frac{\partial a_2}{\partial \xi_j}(X(s), \Xi(s)) \\
\dot{\Xi}(s) = -\frac{\partial a_2}{\partial x_j}(X(s), \Xi(s))
\end{cases}
\]

The hypothesis on the principal symbol imply that $\lim_{s \to +\infty} |X(s; y_0, \eta_0)| = +\infty$.

We set
\[ \Gamma_{\varepsilon_0}^\pm(y_0, \eta_0) = \bigcup_{s \leq 0} \left\{ x \in \mathbb{R}^n \mid |x - X(\pm s; y_0, \eta_0)| \leq \varepsilon (1 + |s|) \right\}. \]

For $\varepsilon \in \mathbb{R}$ denote
\[ \phi_\varepsilon(x, \xi) = x \cdot \xi - i\varepsilon \frac{\theta(x, \xi)}{\langle x \rangle^{1-\sigma} \langle \xi \rangle^{1-\delta}}, \]
where $\sigma > 0$, $\delta \geq 0$ and $\sigma + \delta = \kappa$, $\kappa < 1$, and define
\[ I_{\phi_\varepsilon}(x, D)u(x) = \int_{\mathbb{R}^n} e^{i\phi_\varepsilon(x, \xi)} \hat{u}(\xi) d\xi, \]
where $\hat{u}(\xi)$ stands for a Fourier transform of $u$ and $d\xi = (2\pi)^{-n} d\xi$.

**Theorem.** Assume that Assumptions I and II are satisfied for $d\kappa \leq 1$, $\kappa < 1$ and $d \geq 1$.
If $u_0 \in L^2(\mathbb{R}^n)$ and $I_{\phi_\varepsilon}(x, D)u_0 \in L^2(\Gamma_{\varepsilon_0}^\pm(y_0, \eta_0))$, for $|\varepsilon| \leq \varepsilon_0$, then there exists a solution $u$ of (1) such that $(y_0, \eta_0) \notin \text{WF}_{1/\kappa} u(t, \cdot)$, for all $t > 0$.
