Optimal Control Problems for Distributed Hopfield-type Neural Networks

1 Introduction

The stability properties of lumped Hopfield-type neural networks have been studied extensively and the results as well as the application to optimization problems are reported in many references (see the references in Vanualailai, Nakagiri and Soma [12]). In this paper we study a model which involves spatial distributions of neural networks described by the dynamics of n-numbers of neurons. The distributive model may be consider as an analogous model of the Hodgkin-Huxley equation and the Fitz-Hugh-Nagumo equation which describe the nerve impulse transmissions (cf. Hodgkin and Huxley [6], Fitz-Hugh [5], Nagumo [9]). The purpose of this paper is to study the optimal control problems for the systems governed by distributed models of Hopfield-type neural networks.

Let $\Omega$ be an open bounded domain of $\mathbb{R}^m$ and $\partial \Omega = \Gamma$ be the boundary of $\Omega$. Let $T > 0$ and let $Q = \Omega \times (0, T)$ and $\Sigma = \Gamma \times (0, T)$. Let $y_i$ denotes the activation potential of the $i$-th neurons, which is a functions of time $t$ and the place $x \in \Omega$, $i = 1, 2, \ldots, n$. The distributed Hopfield-type model of coupled n-numbers of neurons is described by

$$
\begin{align}
\frac{\partial y_i}{\partial t} - d_i \Delta y_i &= -a_i y_i + \sum_{j=1}^{n} c_{ijj} F_j(y_j) + g_i \quad \text{in } Q, \\
\frac{\partial y_i}{\partial \eta} &= k_i \quad \text{on } \Sigma, \\
y_i(0, x) &= y_0^i \quad \text{in } \Omega, \quad i = 1, 2, \ldots, n.
\end{align}
$$

Here in (1.1) the constants $a_i > 0$, $c_{ij}$ are the same as explained in [12], $d_i > 0$ are diffusion constants, $g_i$ are forcing input, $k$ are the Neumann inputs, $y_0^i$ are initial values and $F_j : \mathbb{R} = (-\infty, \infty) \rightarrow (-1, 1)$ are nonlinear activation functions.

We consider the quadratic optimal control problem for (1.1). The control system under consideration is given by (1.1) in which $g_i$, $k_i$ and $y_0^i$ are replaced by the control variables $B_i^0 u_i^0$, $B_i^1 u_i^1$ and $E_i w_i$, respectively. Here $B_i^0, B_i^1$ and $E_i$ are distributed, boundary and initial controllers and $u_i^0, u_i^1$ and $w_i$ are respective control variables. Let $\mathcal{U}_i^0, \mathcal{U}_i^1$ and $\mathcal{W}_i$ be the Hilbert spaces of control variables $u_i^0, u_i^1$ and $w_i$. We denote

$$\mathcal{U}^0 = \prod_{i=1}^{n} \mathcal{U}_i^0, \quad \mathcal{U}^1 = \prod_{i=1}^{n} \mathcal{U}_i^1, \quad \mathcal{W} = \prod_{i=1}^{n} \mathcal{W}_i$$

and $u_0 = (u_0^0, u_0^1, \ldots, u_0^n)$, $u_1 = (u_1^0, u_1^1, \ldots, u_1^n)$, $w = (w_1, w_2, \ldots, w_n)$. We set the product Hilbert space $\mathcal{U} = \mathcal{U}^0 \times \mathcal{U}^1 \times \mathcal{W}$ of control variables $u = (u_0, u_1, w) \in \mathcal{U}$. 

神戸大学自然科学研究所　王　全芳 (Quan-Fang Wang)
神戸大学工学部　中村信一 (Shin-ichi Nakagiri)
Let \( y = y(u) = (y_1(u), y_2(u), \ldots, y_n(u))^T \) be the solution state of control system for a given \( u \in \mathcal{U} \). The quadratic cost function attached to the system is given by

\[
J(u) = \sum_{i=1}^{n} \int_{Q} |y_i(u) - z_{id}^0|^2 dx dt + \sum_{i=1}^{n} \int_{\Omega} |y_i(u, T) - z_{id}^1|^2 dx + (Nu, u)_\mathcal{U},
\]

for all \( u = (u_0, u_1, w) \in \mathcal{U} \), \( i = 1, 2, \ldots, n \) are desired values, and \( N \in \mathcal{L}(\mathcal{U}) \) is symmetric and positive. Let \( \mathcal{U}_{ad} \) be an admissible subset of \( \mathcal{U} \). The optimal control problem is to find and characterize an element \( u^* = (u_0^*, u_1^*, w^*) \in \mathcal{U}_{ad} \), called the optimal control, such that

\[
\inf_{u \in \mathcal{U}_{ad}} J(u) = J(u^*). \tag{1.3}
\]

In this paper we shall solve this quadratic cost optimal control problem for the distributed model of Hopfield-type neural networks (1.1). For the purpose we state the basic results on the existence and uniqueness of weak solutions for the nonlinear system (1.1) in the framework of Dautray and Lions [4]. After that we prove the existence of an optimal control for (1.2). The main contribution is to construct the adjoint state systems and to establish the necessary conditions of optimality for the quadratic cost (1.2). For the related works on optimal control theory of nonlinear parabolic equations, we refer to [1], [2], [3], [13], [14].

## 2 Existence and Uniqueness of weak solutions

In this section we shall give the results on existence, uniqueness and regularity of solution for the uncontrolled (free) system (1.1) based on the variational formulation of systems due to Dautray and Lions [4].

For the nonlinear function \( F_j(s) \), we suppose the uniform Lipschitz continuity:

\[
\exists K > 0 : |F_j(s) - F_j(r)| \leq K|s - r|, \quad j = 1, 2, \ldots, n. \tag{2.1}
\]

For the evolution equation setting of (1.1), we introduce two Hilbert spaces \( H = L^2(\Omega) \) and \( V = H^1(\Omega) \) according to the Neumann boundary condition in (1.1). We endow those space with the usual inner products and norms

\[
(\psi, \phi) = \int_{\Omega} \psi(x)\phi(x) dx, \quad |\psi| = (\psi, \psi)^{\frac{1}{2}} \quad \text{for all} \quad \psi, \phi \in H,
\]

\[
(\psi, \phi) = \int_{\Omega} \psi(x)\phi(x) dx + \sum_{i=1}^{n} \int_{\Omega} \frac{\partial}{\partial x_i} \psi(x) \frac{\partial}{\partial x_i} \phi(x) dx \quad \text{for all} \quad \psi, \phi \in H^1(\Omega),
\]

respectively. Let us introduce the product Hilbert spaces \( \mathcal{V} = (H^1(\Omega))^n, \mathcal{H} = (L^2(\Omega))^n \) with the inner products defined by

\[
(\phi, \psi)_{\mathcal{H}} = \sum_{i=1}^{n} (\phi_i, \psi_i), \quad \phi = (\phi_1, \phi_2, \ldots, \phi_n)^T, \quad \psi = (\psi_1, \psi_2, \ldots, \psi_n)^T \in \mathcal{H}
\]
\[(\phi, \psi)_V = \sum_{i=1}^{n} (\phi_i, \psi_i) + \sum_{i=1}^{n} (\phi_i, \psi_i), \quad \phi = (\phi_1, \phi_2, \ldots, \phi_n)^T, \quad \psi = (\psi_1, \psi_2, \ldots, \psi_n)^T \in V,\]

respectively. Then the dual space of \(V\) is given by \(V^\prime = (V')^n\) and the dual pairing between \(V^\prime\) and \(V\) is given by

\[(\phi, \psi)_{V, V^\prime} = \sum_{i=1}^{n} (\phi_i, \psi_i), \quad \forall \phi = (\phi_1, \phi_2, \ldots, \phi_n)^T \in V, \quad \psi = (\psi_1, \psi_2, \ldots, \psi_n)^T \in V^\prime,\]

where \((\phi_i, \psi_i)\) denotes the dual pairing between \(V\) and \(V^\prime\) of \(\phi_i \in V\) and \(\psi_i \in V^\prime\). The norms of \(V\) and \(H\) are denoted by \(\|\psi\|_V\) and \(\|\psi\|_H\), respectively.

For the sake of simplicity of notations, we introduce the following vector and matrix representations:

\[
y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}, \quad \Delta y = \begin{bmatrix} \Delta y_1 \\ \Delta y_2 \\ \vdots \\ \Delta y_n \end{bmatrix}, \quad C = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & c_{nn} \end{bmatrix}, \quad F(y) = \begin{bmatrix} F_1(y_1) \\ F_2(y_2) \\ \vdots \\ F_n(y_n) \end{bmatrix}, \quad (2.2)
\]

\[
D = \text{diag} \{d_1, d_2, \ldots, d_n\}, \quad A = \text{diag} \{a_1, a_2, \ldots, a_n\}, \quad g = (g_1, g_2, \ldots, g_n)^T, \quad k = (k_1, k_2, \ldots, k_n)^T \text{ and } y_0 = (y_0^1, y_0^2, \ldots, y_0^n)^T. \text{ Then the system (1.1) is rewritten simply by}
\[
\begin{aligned}
\frac{\partial y}{\partial t} - D \Delta y &= Ay + CF(y) + g \quad \text{in } Q, \\
\frac{\partial y}{\partial \eta} &= k \quad \text{on } \Sigma, \\
y(0, x) &= y_0 \quad \text{in } \Omega.
\end{aligned} \quad (2.3)
\]

Now we give the definition of a weak solution of (2.3). First we introduce the Hilbert space

\[
W(0, T; V, V') = \{g \mid g \in L^2(0, T; V), \quad g' \in L^2(0, T; V')\}.
\]

The inner product and the induced norm in \(W(0, T; V, V')\) are defined respectively by

\[
(g_1, g_2)_{W(0, T; V, V')} = \int_0^T \{(g_1(t), g_2(t))_V + (g_1'(t), g_2'(t))_{V'}\} dt,
\]

\[
\|g\|_{W(0, T; V, V')} = \left( \|g\|^2_{L^2(0, T; V)} + \|g'\|^2_{L^2(0, T; V')} \right)^{\frac{1}{2}}.
\]

The space \(W(0, T; V, V')\) can be identified with \(W(0, T; V, V')^n\), and for simplify, we denote it by \(W(0, T)\). Also we define the Hilbert spaces \(H^{\frac{1}{2}}(\Gamma)\) and its dual \(H^{-\frac{1}{2}}(\Gamma)\) by \((H^{\frac{1}{2}}(\Gamma))^n\) and \((H^{-\frac{1}{2}}(\Gamma))^n\), respectively. The dual pairing between \(H^{\frac{1}{2}}(\Gamma)\) and \(H^{-\frac{1}{2}}(\Gamma)\) is defined by

\[
(\phi, \psi)_{H^{\frac{1}{2}}(\Gamma), H^{-\frac{1}{2}}(\Gamma)} = \sum_{i=1}^{n} (\phi_i, \psi_i)_\Gamma, \quad \forall \phi = (\phi_1, \phi_2, \ldots, \phi_n)^T \in H^{\frac{1}{2}}(\Gamma), \quad \psi = (\psi_1, \psi_2, \ldots, \psi_n)^T \in H^{-\frac{1}{2}}(\Gamma)
\]
where \((\phi_i, \psi_i)_\Gamma\) denotes the dual pairing between \(H^\frac{1}{2}(\Gamma)\) and \(H^{-\frac{1}{2}}(\Gamma)\) of \(\phi_i\) and \(\psi_i\). Since \(F_j : R \rightarrow (-1, 1), j = 1, 2, ..., n\), we see from (2.1) that \(F : \mathcal{H} \rightarrow \mathcal{H}\) and

\[
|F(\psi)|^2_{\mathcal{H}} = \int_{\Omega} |F(\psi)|^2 dx \leq n|\Omega|, \quad \forall \psi \in \mathcal{H}, \quad (2.4)
\]

and by (2.1), we have

\[
|F(\phi) - F(\psi)|_{\mathcal{H}} \leq K|\phi - \psi|_{\mathcal{H}}, \quad \forall \phi, \psi \in \mathcal{H}. \quad (2.5)
\]

**Definition 1** A function \(y\) is said to be a weak solution of (2.3) if \(y \in W(0, T)\) and \(y\) satisfies

\[
\begin{cases}
(y', v)_\mathcal{V}, \mathcal{V} + (Dy', \nabla v)_\mathcal{H} = (Ay, v)_\mathcal{H} + (CF(y), v)_\mathcal{H} + (g, v)_\mathcal{V}, v + (k, v|_{\Gamma})_{H^{-\frac{1}{2}}(\Gamma), H^\frac{1}{2}(\Gamma)} \\
y(0) = y_0 \in \mathcal{H}.
\end{cases}
\]

for all \(v \in \mathcal{V}\) in the sense of \(\mathcal{D}'(0, T)\), \( (2.6)\)

Here in (2.6), \(\mathcal{D}'(0, T)\) denotes the space of distributions on \((0, T)\). Also we note that the trace \(v|_\Gamma\) of \(v \in \mathcal{V}\) on \(\Gamma\) belongs to \(H^\frac{1}{2}(\Gamma)\).

For the existence and uniqueness of weak solution for (1.1), we can give the following theorem.

**Theorem 1** Assume that \(y_0 \in \mathcal{H}, \ g \in L^2(0, T; \mathcal{V}'), \ k \in L^2(0, T; \mathcal{H}^{-\frac{1}{2}}(\Gamma))\). Then the problem (2.3) has a unique weak solution \(y\) in \(W(0, T)\), which belongs to \(C([0, T]; \mathcal{H})\). Further, we have the estimate

\[
\|y\|_{L^\infty (0, T; \mathcal{H})}, \quad \|y\|_{W(0, T)}^2 \leq C \left( 1 + |y_0|^2_{\mathcal{H}} + \|g\|_{L^2(0, T; \mathcal{V}')}^2 + \|k\|_{L^2(0, T; \mathcal{H}^{-\frac{1}{2}}(\Gamma))}^2 \right), \quad (2.7)
\]

where \(C > 0\) depends only on \(a_i, c_{ij}\) and \(d_i\).

### 3 Optimal control problems

In this section we study the quadratic optimal control problem for (1.1) by means of distributive, boundary and initial controls. Let \(B^0_i \in \mathcal{L}(\mathcal{U}_i^0, L^2(0, T; \mathcal{V}'))\), \(B^1_i \in \mathcal{L}(\mathcal{U}_i^1, L^2(0, T; H^\frac{1}{2}(\Gamma))\) and \(E_i \in \mathcal{L}(W_i, H)\) for \(i = 1, 2, ..., n\). We denote

\[
B^0 = \text{diag} \{B^0_1, B^0_2, ..., B^0_n\}, \quad B^1 = \text{diag} \{B^1_1, B^1_2, ..., B^1_n\}, \quad E = \text{diag} \{E_1, E_2, ..., E_n\}, \quad (3.1)
\]

respectively. Then \(B^0, B^1\) and \(E\) are operators satisfying \(B^0 \in \mathcal{L}(\mathcal{U}^0, L^2(0, T; \mathcal{V}'))\), \(B^1 \in \mathcal{L}(\mathcal{U}^1, L^2(0, T; H^\frac{1}{2}(\Gamma))\) and \(E \in \mathcal{L}(\mathcal{V}, \mathcal{H})\), which are called the controllers. We consider the following control system described by

\[
\begin{cases}
\frac{\partial y}{\partial t} - D\Delta y = Ay + CF(y) + B^0u_0 \quad \text{in } Q, \\
\frac{\partial y}{\partial n} = B^1u_1 \quad \text{on } \Sigma, \\
y(0, x) = Ew \quad \text{in } \Omega.
\end{cases} \quad (3.2)
\]

For any \(u = (u_0, u_1, w) \in \mathcal{U}\), by virtue of Theorem 1, we have a unique weak solution \(y = y(u)\) of (3.2) in \(W(0, T)\). Hence we can define the solution map \(u \rightarrow y(u)\) of \(\mathcal{U}\) into \(W(0, T)\). We
shall call $y(u)$ the state of the control system (3.2). The quadratic cost function associated with the control system (3.2) is given by (1.2), and is written in compact form

$$J(u) = \|y(u) - z_d^0\|^2_{L^2(Q)} + \|y(u, T) - z_d^1\|^2_{L^2(\Omega)} + (Nu, u)_\Omega, \forall u = (u_0, u_1, w) \in \mathcal{U}, \quad (3.3)$$

where $z_d^0 = (z_{1d}, z_{2d}, \ldots, z_{nd})^T \in (L^2(Q))^n$, $z_d^1 = (z_{1d}, z_{2d}, \ldots, z_{nd})^T \in (L^2(\Omega))^n$ are desired values and $N = (N^0, N^1, N^2) \in \mathcal{L}(\mathcal{U}) \times \mathcal{L}(\mathcal{U}^1) \times \mathcal{L}(W)$. We suppose that each $N^j (j = 0, 1, 2)$ is symmetric and positive. Since $y \in W(0, T) \subset L^2(0, T; \mathcal{H}) = (L^2(Q))^n$ and $y(u, T) \in \mathcal{H} = (L^2(\Omega))^n$ by Theorem 1, the cost (3.3) is meaningful for any $u \in \mathcal{U}$.

Let $\mathcal{U}_{ad}$ be a closed convex subset of $\mathcal{U}$, which is called the admissible set. We shall solve the following two fundamental problems for the control system (3.2) attached the quadratic cost (3.3):

(i) Existence problem of an element $u^* = (u^*_0, u^*_1, w^*) \in \mathcal{U}_{ad}$ such that

$$\inf_{u \in \mathcal{U}_{ad}} J(u) = J(u^*);$$

(ii) Characterization problem of such $u^*$.

Such a $u^*$ in (i) is called the optimal control for the system (3.2) with the cost (3.3).

### 3.1 Existence of optimal control

First we solve the existence problem (i) in the following theorem.

**Theorem 2** Assume that $\mathcal{U}_{ad}$ is a non-empty bounded closed convex set of $\mathcal{U}$. Then there exists at least one optimal control $u^*$ for the control problem (3.2) with the cost (3.3).

**Proof:** Set $J = \inf_{u \in \mathcal{U}_{ad}} J(u)$. Since $\mathcal{U}_{ad}$ is non-empty, there is a sequence $\{u_n\}$ in $\mathcal{U}_{ad}$ such that

$$\inf_{u \in \mathcal{U}_{ad}} J(u) = \lim_{n \to \infty} J(u_n) = J.$$

Obviously, $\{J(u_n)\}$ is bounded in $\mathbb{R}^+$. Since $\mathcal{U}_{ad}$ is bounded closed and convex, we can choose a subsequence $\{u_m\} = \{u_{m0}, u_{m1}, w_m\}$ of $\{u_n\}$ and find a $u^* = (u^*_0, u^*_1, w^*) \in \mathcal{U}_{ad}$ such that

$$u_m \to u^* \text{ weakly in } \mathcal{U} \text{ as } m \to \infty. \quad (3.4)$$

By the estimate (2.7) in Theorem 1, we have for $y = y(u)$ that

$$\|y\|^2_{L^\infty(0, T; \mathcal{H})}, \|y\|^2_{W(0, T)} \leq C(1 + |Ew|^2_{\mathcal{H}} + \|B^0u_0\|^2_{L^2(0, T; \mathcal{V}')}) + \|B^1u_1\|^2_{L^2(0, T; \mathcal{H}^{-1/2}(\Gamma))}. \quad (3.5)$$

Since $\mathcal{U}_{ad}$ is bounded, we see from (3.5) that $\{y(u_m)\}$ is bounded in $W(0, T)$. Hence we can choose a subsequence $\{y(u_{mk})\}$ of $\{y(u_m)\}$ and find a $z \in W(0, T)$ such that

$$y(u_{mk}) \to z \text{ weakly in } W(0, T). \quad (3.6)$$

For simplicity let us denote $y_{mk} = y(u_{mk})$. By the compactness of embedding $V \to H$, the embedding $V \to \mathcal{H}$ is compact too. Thus, by the compactness embedding theorem due to the Aubin-Lions-Temam (cf. Temam [11, p.274]), we can suppose

$$y_{mk} \to z \text{ strongly in } L^2(0, T; \mathcal{H}). \quad (3.7)$$
By the uniformly Lipschitz continuity (2.5), it follows from (3.7) that
\[ F(y_{mk}) \to F(z) \quad \text{strongly in} \quad L^2(0, T; \mathcal{H}). \] (3.8)

By (3.6), we see that \( y'_{mk} \to z' \) weakly in \( L^2(0, T; \mathcal{V}') \) and \( \nabla y_{mk} \to \nabla z \) weakly in \( L^2(0, T; \mathcal{H}) \).

Hence by the definition of weak solutions, we have
\[
\int_0^T \{ (y_{mk}', \phi)_{\mathcal{V}', \mathcal{V}} + (D\nabla y_{mk}, \nabla \phi)_{\mathcal{H}} \} dt
= \int_0^T \{ (Ay_{mk}, \phi)_{\mathcal{H}} + (CF(y_{mk}), \phi)_{\mathcal{H}} + (B^0 u^0_{mk}, \phi)_{\mathcal{H}} + (B^1 u^1_{mk}, \phi|_\Gamma)_{\mathcal{H}^{-\frac{1}{2}}(\Gamma), \mathcal{H}^{\frac{1}{2}}(\Gamma)} \} dt,
\forall \phi \in L^2(0, T; \mathcal{V}). \] (3.9)

Therefore, by taking \( k \to \infty \) in (3.9) and using (3.4) and (3.8), we can deduce
\[
\int_0^T \{ (z', \phi)_{\mathcal{V}', \mathcal{V}} + (D\nabla z, \nabla \phi)_{\mathcal{H}} \} dt
= \int_0^T \{ (Az, \phi)_{\mathcal{H}} + (CF(z), \phi)_{\mathcal{H}} + (B^0 u^0, \phi)_{\mathcal{H}} + (B^1 u^1, \phi|_\Gamma)_{\mathcal{H}^{-\frac{1}{2}}(\Gamma), \mathcal{H}^{\frac{1}{2}}(\Gamma)} \} dt,
\forall \phi \in L^2(0, T; \mathcal{V}). \] (3.10)

This implies, by the standard manipulation as in Dautray and Lions [4], that \( z \) satisfies
\[
\langle z', \phi \rangle_{\mathcal{V}', \mathcal{V}} + (D\nabla z, \nabla \phi)_{\mathcal{H}}
= (Az, \phi)_{\mathcal{H}} + (CF(z), \phi)_{\mathcal{H}} + (B^0 u^0, \phi)_{\mathcal{H}} + (B^1 u^1, \phi|_\Gamma)_{\mathcal{H}^{-\frac{1}{2}}(\Gamma), \mathcal{H}^{\frac{1}{2}}(\Gamma)}, \quad \forall \phi \in \mathcal{V},
\] in \( \mathcal{D}(0, T) \). It is not difficult to verified that \((y_{mk}(0), \nu)_{\mathcal{H}} = (Ew_{mk}, \nu)_{\mathcal{H}} \to (z(0), \nu)_{\mathcal{H}} = (Ew^*, \nu)_{\mathcal{H}} \) for any \( \nu \in \mathcal{V} \). So that \( z(0) = Ew^* \).

Hence from the uniqueness of weak solution for the system (3.2), we have \( z = y(u^*) \). Then from (3.6) and (3.7) we see
\[
y(u_{mk}) \to y(u^*) \quad \text{strongly in} \quad L^2(0, T; H) = (L^2(\Omega))^n, \] (3.11)
\[
y(u_{mk}, T) \to y(u^*, T) \quad \text{weakly in} \quad \mathcal{H} = (L^2(\Omega))^n. \] (3.12)

By (3.11) and (3.12), we have
\[
\lim_{m \to \infty} \| y(u_{mk}) - z^0_d \|_{(L^2(\Omega))^n} = \| y(u^*) - z^0_d \|_{(L^2(\Omega))^n} \] (3.13)

Since the norm \( \| \cdot \|_{(L^2(\Omega))^n} \) is lower semi-continuous in the weak topology of \( \mathcal{H} = (L^2(\Omega))^n \), we have
\[
\liminf_{m \to \infty} \| y(u_{mk}, T) - z^1_d \|_{(L^2(\Omega))^n} \geq \| y(u^*, T) - z^1_d \|_{(L^2(\Omega))^n}. \] (3.14)

On the other hand, the weak convergence (3.4) and boundedness of \( N \) imply
\[
\liminf_{m \to \infty} (Nu_{mk}, u_{mk})_\mathcal{U} \geq (Nu^*, u^*). \] (3.15)

Therefore \( J = \liminf_{m \to \infty} J(u_{mk}) \geq J(u^*) \), and hence \( J(u^*) = \inf_{u \in \mathcal{U}_{ad}} J(u) \). This proves that \( u^* \) is an optimal control for the cost (3.3). This completes the proof of Theorem 2.
3.2 Necessary optimality conditions

In this subsection we consider the problem (ii). It is well known (cf. Lions [7]) that the optimality condition for \( u^* \) is given by the variational inequality

\[
J'(u^*)(u - u^*) \geq 0 \quad \text{for all } u \in U_{ad},
\]

(3.16)

where \( J'(u^*) \) denotes the Gâteaux derivative of \( J(u) \) in (3.3) at \( u^* \). The objective of this subsection is to write down the optimality condition (3.16) in terms of proper adjoint state systems. So we need to calculate the Gâteaux derivative of \( y(u) \) at \( u = u^* \). For the purpose we have to prepare the following propositions:

**Proposition 1** Let \( y_1 \) and \( y_2 \) be two weak solutions of (3.2) with control variables \( u_1 = (u_0^1, u_1^1, w^1) \) and \( u_2 = (u_0^2, u_1^2, w^2) \), respectively. Then \( z = y_1 - y_2 \) satisfies the following equality for all \( t \in [0, T] \):

\[
\frac{1}{2}||z(t)||_H^2 + \int_0^t |\sqrt{D} \nabla z|_H^2 dt = \frac{1}{2}||Ew_1 - Ew_2||_H^2 + \int_0^t (C(F(y_1) - C(F(y_2)), z)_H dt \\
+ \int_0^t (B^0 u_0^1 - B^0 u_0^2, z)_{\nu t} dt + \int_0^t (B^1 u_1^1 - B^1 u_1^2, z|_{\Gamma})_{\mathcal{H}^{-\frac{1}{2}}(\Gamma), \mathcal{H}^\frac{1}{2}(\Gamma)} dt.
\]

(3.17)

This proposition follows from the energy equalities for \( y_1 \) and \( y_2 \).

**Proposition 2** Let \( v_0 \in U \) be fixed. Then

\[
y(u + \lambda v_0) \to y(u) \quad \text{strongly in } C([0, T]; H) \quad \text{and } L^2(0, T; V) \quad \text{as } \lambda \to 0.
\]

(3.18)

**Proof:** For \( \lambda \in (0, 1] \), let \( y(u + \lambda v_0) \) and \( y(u) \) be the weak solutions of (3.2) for \( u \) and \( v_0 = (u_0^0, u_1^0, w^0) \) in \( U \). Set \( y_\lambda = y(u + \lambda v_0) - y(u) \). Then \( y_\lambda \) is a weak solution of

\[
\begin{aligned}
\frac{d}{dt} y_\lambda &= D\Delta y_\lambda + Ay_\lambda + C(F(y(u + \lambda v_0)) - C(F(y(u))) + \lambda B^0 u_0^0 \quad \text{in } Q, \\
\frac{\partial y_\lambda}{\partial \eta} &= \lambda B^1 u_1^0 \quad \text{on } \Sigma, \\
y_\lambda(0, x) &= \lambda Ew^0 \quad \text{in } \Omega.
\end{aligned}
\]

(3.19)

Since the nonlinear term satisfies the Lipschitz continuity (2.5), we have

\[
|\langle C(F(y(u + \lambda v_0) - C(F(y(u))), y_\lambda)\rangle_H | \\
\leq ||C|| \cdot ||F(y(u + \lambda v_0) - F(y(u)))|_H |y_\lambda|_H \leq K||C|| ||y_\lambda||_H^2
\]

(3.20)

Using (3.20), we can deduce by Proposition 1 that

\[
||y_\lambda||_{L^2(0, T; V)}, ||y_\lambda||_{L^\infty(0, T; H)}, \leq C\lambda (||Ew^0||_H^2 + ||B^0 u_0^0||_{L^2(0, T; V)}^2 + ||B^1 u_1^0||_{L^2(0, T; H^{-\frac{1}{2}}(\Gamma))}^2).
\]

(3.21)

This means that

\[
y_\lambda \to 0 \quad \text{strongly in } L^\infty(0, T; H) \cap L^2(0, T; V)
\]
as $\lambda \to 0$. Now it is obviously by the inclusion $C([0,T];\mathcal{H}) \subset W(0,T)$ that

$$y_\lambda \to 0 \text{ strongly in } C([0,T];\mathcal{H})$$

as $\lambda \to 0$. This proves Proposition 2.

In this subsection we further assume that $F_j \in C^1(\mathbb{R})$ and

$$\exists K > 0: |F_j'(s)| \leq K, \ j = 1, 2, \ldots, n. \quad (3.22)$$

Then for any $y \in \mathcal{H}$, $F$ is Gâteaux differentiable and the derivative $\partial_yF(y) \in \mathcal{L}(\mathcal{H})$ is given by

$$\partial_yF(y)z = \left( \begin{array}{c} F_1'(y_1)z_1 \\ F_2'(y_2)z_2 \\ \vdots \\ F_n'(y_n)z_n \end{array} \right), \ \forall z = (z_1, z_2, \ldots, z_n)^T \in \mathcal{H}, \quad (3.23)$$

where $y = (y_1, y_2, \ldots, y_n)^T \in \mathcal{H}$ and the multiplication operators $F_j'(y_j) : H \to H$ are bounded for all $j = 1, 2, \ldots, n$. We remark that (3.22) is stronger than (2.5) and $\|\partial_yF(y)\|_{\mathcal{L}(\mathcal{H})} \leq K$.

Theorem 3 Assume (3.22). Then the map $u \to y(u)$ of $\mathcal{U}$ into $W(0,T)$ is weakly Gâteaux differentiable at $u^* = (u_0^*, u_1^*, w^*)$ and such the Gâteaux derivative of $y(u)$ at $u^*$ in the direction $u - u^* \in \mathcal{U}$, say $z = Dy(u^*)(u - u^*) \in W(0,T)$, is a unique weak solution of the following equation

$$\begin{aligned}
\begin{cases}
\frac{\partial z}{\partial t} - D\Delta z &= A z + C\partial_yF(y(u))z + B^0(u_0 - u_0^*) \quad \text{in } Q, \\
\frac{\partial z}{\partial \eta} &= B^1(u_1 - u_1^*) \quad \text{on } \Sigma,
\end{cases}
\end{aligned}
\quad (3.24)$$

Proof: Let $u = (u_0, u_1, w), u^* = (u_0^*, u_1^*, w^*)$ and $v_0 = u - u^* = (u_0^0, u_1^0, w^0)$. Let $y(u^* + \lambda v_0)$ and $y(u^*)$ be the solution of (3.1) corresponding to $u^* + \lambda v_0$ and $u^*$ in $\mathcal{U}_{ad}$, respectively. Set $y_\lambda = y(u^* + \lambda v_0) - y(u^*)$ and $z_\lambda = \frac{y_\lambda}{\lambda}$, then $z_\lambda$ satisfies

$$\begin{aligned}
\begin{cases}
\frac{\partial z_\lambda}{\partial t} - D\Delta z_\lambda &= A z_\lambda + C \lambda^{-1}(F(y(u^* + \lambda v_0)) - F(y(u^*))) + B^0u_0^0 \quad \text{in } Q, \\
\frac{\partial z_\lambda}{\partial \eta} &= B^1u_1^0 \quad \text{on } \Sigma,
\end{cases}
\end{aligned}
\quad (3.25)$$

in the weak sense. By substituting $v = z_\lambda$ in the weak form of (3.25) and integrating it over $[0,T]$, we have

$$\int_0^T \langle z_\lambda', z_\lambda \rangle_{\mathcal{V}, \mathcal{V}} + \langle D\nabla z_\lambda, \nabla z_\lambda \rangle_{\mathcal{H}} dt$$

$$= \int_0^T \langle Az_\lambda, z_\lambda \rangle_{\mathcal{H}} dt + \int_0^T \langle C \lambda^{-1}(F(y(u^* + \lambda v_0)) - F(y(u^*))), z_\lambda \rangle_{\mathcal{H}} dt$$

$$+ \int_0^T \langle B^0u_0^0, z_\lambda \rangle dt + \int_0^T \langle B^1u_1^0, z_\lambda \rangle_{\mathcal{H}^{-1}((\Gamma), \mathcal{H}^{\frac{1}{2}}(\Gamma))} dt. \quad (3.26)$$
From (2.5), we have the estimate
\[
|\langle F(y(u^* + \lambda v_0)) - F(y(u^*)), z_{\lambda} \rangle_{\mathcal{H}}| \leq K \| z_{\lambda} \|^2_{\mathcal{H}}.
\] (3.27)

By (3.26) and (3.27), we can verify the boundedness of \( \{z_{\lambda} \} \) in \( W(0,T) \). Hence by the compactness theorem there exists a \( z \in W(0,T) \) and a subsequence \( \{z_{\lambda_k} \} \) of \( \{z_{\lambda} \} \) such that
\[
z_{\lambda_k} \rightarrow z \text{ weakly in } W(0,T),
\] (3.28)
\[
z_{\lambda_k} \rightarrow z \text{ strongly in } L^2(0,T;\mathcal{H})
\] (3.29)
as \( \lambda_k \rightarrow 0 \). Since \( L^2(0,T;\mathcal{H}) = (L^2(Q))^n \), it follows from (3.29) that, if necessary by taking subsequence of \( \{\lambda_k \} \),
\[
z_{\lambda_k} \rightarrow z \quad \text{a.e. in } Q
\] (3.30)
as \( \lambda_k \rightarrow \infty \). For any \( \phi \in L^2(0,T;\mathcal{V}) \subset L^2(0,T;\mathcal{H}) \), \( z_{\lambda_k} \) satisfies
\[
\int_0^T \langle z'_{\lambda_k}(t) + Dz_{\lambda_k}(t), \phi(t) \rangle_{\mathcal{V}',\mathcal{V}} dt
\]
\[
= \int_0^T \langle Az_{\lambda_k}, \phi(t) \rangle_{\mathcal{H}} dt + \int_0^T \frac{\langle F(y(u^* + \lambda_k v_0)) - F(y(u^*)), \phi(t) \rangle_{\mathcal{H}}}{\lambda_k} dt
\]
\[
+ \int_0^T \langle B^0 u^0, \phi(t) \rangle_{\mathcal{V}',\mathcal{V}} dt + \int_0^T \langle B^1 u^1, \phi(t) \rangle_{\mathcal{V}',\mathcal{V}} dt
\] (3.31)

Now we shall prove that
\[
\frac{1}{\lambda_k} \{ F(y(u^* + \lambda_k v_0)) - F(y(u^*)) \} \rightarrow \partial_y F(y(u))z \text{ strongly in } L^2(0,T;\mathcal{H}).
\] (3.32)

By the mean value theorem, there exist \( \theta_1, \theta_2, \ldots, \theta_n \in [0,1] \) such that
\[
\frac{1}{\lambda_k} \{ F(y(u^* + \lambda_k v_0; t, x)) - F(y(u^*; t, x)) \} = \partial_y F(y_{\theta_k}(t, x)) z_{\lambda_k}(t, x)
\] (3.33)
where \( y_{\theta_k}(t, x) = (\theta_1 y_1(u^*; t, x) + (1 - \theta_1)y_1(u^* + \lambda_k v_0; t, x), \ldots, \theta_n y_n(u^*; t, x) + (1 - \theta_n)y_n(u^* + \lambda_k v_0; t, x))^T \). By (3.30), we can see easily that
\[
y_{\theta_k}(t, x) \rightarrow y(u^*; t, x) \quad \text{a.e. in } Q.
\] (3.34)

Since \( F_j \) are continuously differentiable for all \( j = 1, 2, \ldots, n \), we have by (3.30), (3.33) and (3.34) that
\[
\frac{1}{\lambda_k} \{ F(y(u^* + \lambda_k v_0; t, x)) - F(y(u^*)) \} \rightarrow \partial_y F(y(u^*))z \text{ a.e. in } Q.
\] (3.35)

It is verified by \( \| \partial_y F(y_{\theta_k}) \|_{\mathcal{L}(\mathcal{H})}, \| \partial_y F(y(u^*)) \|_{\mathcal{L}(\mathcal{H})} \leq K \) that
\[
|\partial_y F(y_{\theta_k}) z_{\lambda_k} - \partial_y F(y(u^*)) z|^2 \leq 2K^2 (|z_{\lambda_k}|^2_{\mathcal{H}} + |z|^2_{\mathcal{H}}).
\] (3.36)

Hence by applying the Lebesgue dominated convergence theorem, we deduce from (3.35) and (3.36) that
\[
\lim_{\lambda_k \rightarrow 0} \int_0^T \int_\Omega |\partial_y F(y_{\theta_k}) z_{\lambda_k} - \partial_y F(y(u^*)) z|^2 dx dt = 0.
\] (3.37)
This completes the proof of (3.32). Then we have the convergence
\[ \int_0^T \frac{(C F(y(u^* + \lambda_k v_0) - F(y(u^*)))}{\lambda_k}, \phi(t))_{\mathcal{H}} dt \to \int_0^T (C \partial_y F(y(u^*))z, \phi(t))_{\mathcal{H}} dt \] (3.38)
as \lambda_k \to 0 for any \( \phi \in L^2(0, T; \mathcal{H}) \). Next we show that \( z \) is weak solution of (3.24). By taking \( \lambda_k \to 0 \) in (3.31), we deduce from (3.28) and (3.38) that
\[
\int_0^T \langle z'(t), \phi(t) \rangle_{\mathcal{V}, \mathcal{V}'} dt + \int_0^T (D \nabla z, \nabla \phi(t))_{\mathcal{H}} dt
\]
\[ = \int_0^T (A z, \phi(t))_{\mathcal{H}} dt + \int_0^T (C \partial_y F(y(u^*))z, \phi(t))_{\mathcal{H}} dt
\]
\[ + \int_0^T (B^0 u_0^0, \phi(t))_{\mathcal{V}', \mathcal{V}} dt + \int_0^T \langle B^1 u_1^0, \phi(t) \rangle_{\mathcal{H}^{-1}(\Gamma), \mathcal{H}^{1}(\Gamma)} dt. \] (3.39)
Hence we can conclude from (3.39) that \( z \) satisfies the equation
\[ (z'(t), v)_{\mathcal{V}, \mathcal{V}'} + (D \nabla z, \nabla v) \]
\[ = (A z, v)_{\mathcal{H}} + (C \partial_y F(y(u^*))z, v)_{\mathcal{H}} + (B^0 u_0^0, v)_{\mathcal{V}', \mathcal{V}} + (B^1 u_1^0, v|_\Gamma)_{\mathcal{H}^{-1}(\Gamma), \mathcal{H}^{1}(\Gamma)}, \quad \forall v \in \mathcal{V} \]
in the sense of \( D'(0, T) \). Using integration by parts in (3.39) for \( \phi \in C^1([0, T]; \mathcal{V}) \) we can show \( z(0) = Ew^0 \). Therefore \( z \) is the weak solution of (3.24). This proves Theorem 3.

By Theorem 3, the cost \( J(u) \) is weakly Gâteaux differentiable at \( u \) in the direction \( u - u^* \) and the optimality condition (3.16) is rewritten by
\[ J'(u^*)(u - u^*) \]
\[ = (y(u^*) - z_d^0, Dy(u^*)(u - u^*))_{(L^2(Q))^n} + (y(u^*, T) - z_d^1, Dy(u^*, T)(u - u^*))_{(L^2(\Omega))^n}
\]
\[ + (Nu^*, u - u^*)_{\mathcal{H}}, \quad \forall u = (u_0, u_1, w) \in \mathcal{U}_{ad}. \] (3.40)
Now we can give the necessary condition of optimality for the distributed Hopfield-type neural networks. The condition is represented in terms of the state and adjoint systems and the variational inequality.

**Theorem 4** Assume that all assumptions in Section 3 hold. Then the optimal control \( u^* \in \mathcal{U}_{ad} \) for (3.3) is characterized by the following system of equations and inequality:
\[
\begin{aligned}
\frac{\partial y}{\partial t} - D \Delta y &= Ay + CF(y) + B^0 u_0^* \quad \text{in} \ Q, \\
\frac{\partial y}{\partial \eta} &= B^1 u_1^* \quad \text{on} \ \Sigma, \\
y(0, x) &= E w^* \quad \text{in} \ \Omega.
\end{aligned}
\] (3.41)
\[
\begin{aligned}
- \frac{\partial p}{\partial t} + D \Delta p &= Ap + \partial_y F(y(u^*)) C^* p + y(u^*) - z_d^0 \quad \text{in} \ Q, \\
\frac{\partial p}{\partial \eta} &= 0 \quad \text{on} \ \Sigma, \\
p(u^*, T, x) &= y(u^*, T) - z_d^1 \quad \text{in} \ \Omega.
\end{aligned}
\] (3.42)
\[
(p(u^*, 0), E(w - w^*))_{\mathcal{H}} + \int_0^T \langle p(u^*), B^0 (u_0 - u_0^*) \rangle_{\mathcal{V}', \mathcal{V}} dt
\]
\[ + \int_0^T \langle p(u^*)|_\Gamma, B^1 (u_1 - u_1^*) \rangle_{\mathcal{H}^{1}(\Gamma), \mathcal{H}^{1}(\Gamma)} dt + (Nu^*, u - u^*) \geq 0, \quad \forall u \in \mathcal{U}_{ad}. \] (3.43)
3.3 Bang-Bang property

In this subsection, we consider the special case where $n = 1, \mathcal{U} = L^2(Q) \times L^2(\Sigma) \times L^2(\Omega)$ and

$$\mathcal{U}_{ad} = \mathcal{U}_{ad}^0 \times \mathcal{U}_{ad}^1 \times \mathcal{W}_{ad} = \{ u_0 \mid u_0^0 \leq u_0 \leq u_0^b, \ a.e. \ on \ Q \} \times \{ u_1 \mid u_a^1 \leq u_1 \leq u_b^1, \ a.e. \ on \ \Sigma \} \times \{ w \mid w_a \leq w \leq w_b, \ a.e. \ on \ \Omega \},$$

with $u_0^0, u_0^b \in L^\infty(Q), u_a^1, u_b^1 \in L^\infty(\Sigma), w_a, w_b \in L^\infty(\Omega)$. Assume that $N = 0, E = B^0 = B^1 = I$. Since $\mathcal{U}_{ad}$ is closed and convex in $\mathcal{U}$, then from the necessary condition (3.43), we have

$$(p(u^*, 0), w - w^*)_{L^2(\Omega)} + \int_0^T (p(u^*), u_0 - u_0^*)_{L^2(\Omega)} dt + \int_0^T (p(u^*)|\Gamma, u_1 - u_1^*)_{L^2(\Gamma)} dt \geq 0,$$

$$\forall u = (u_0, u_1, w) \in \mathcal{U}_{ad},$$

where $u^* = (u_0^*, u_1^*, w^*) \in \mathcal{U}_{ad}$. By setting $(u_0^*, u_1^*, w) \in \mathcal{U}_{ad}$ in (3.45), we get

$$(p(u^*, 0), w - w^*)_{L^2(\Omega)} \geq 0, \quad \forall w \in \mathcal{W}_{ad}. \tag{3.46}$$

Similarly by the Lebesgue convergence theorem, we have from (3.45)

$$(p(u^*, t), u_0 - u_0^*)_{L^2(\Omega)} \geq 0, \quad a.e. \ t \in [0, T], \ \forall u_0 \in \mathcal{U}_{ad}^0,$$

$$(p(u^*, t)|\Gamma, u_1 - u_1^*)_{L^2(\Gamma)} \geq 0, \quad a.e. \ t \in [0, T], \ \forall u_1 \in \mathcal{U}_{ad}^1. \tag{3.47}$$

Then we can deduce the following property of $u^*$:

1) if $p(u^*, 0, x) > 0, \ x \in \Omega,$ then $w^*(x) = w_a(x);$  
   if $p(u^*, 0, x) < 0, \ x \in \Omega,$ then $w^*(x) = w_b(x).$

2) if $p(u^*, t, x) > 0, \ (t, x) \in Q,$ then $u_0^*(t, x) = u_0^a(t, x);$  
   if $p(u^*, t, x) < 0, \ (t, x) \in Q,$ then $u_0^*(t, x) = u_0^b(t, x).$

3) if $p(u^*, t, \xi) < 0, \ (t, \xi) \in \Sigma,$ then $u_1^*(t, \xi) = u_1^b(t, \xi);$  
   if $p(u^*, t, \xi) < 0, \ (t, \xi) \in \Sigma,$ then $u_1^*(t, \xi) = u_1^b(t, \xi).$

This fact (3.47) is well known as the Bang-Bang property of optimal control $u^*$. In the case of $n \geq 2$, we can obtain the similar Bang-Bang property for $u^*$ with respect to each component of $u^* = (u_1^*, u_2^*, w^*)$.
