ON A GENERALISATION OF SPHERICAL CODES AND DESIGNS.

RENAUD COULANGEON

ABSTRACT. We introduced with C. Bachoc and G. Nebe a notion of design (resp. code) in Grassmannian spaces. This extends the classical notions of spherical design (resp. code), which in this setting corresponds to the Grassmannian space $G_{1,n}$, the set of lines in $\mathbb{R}^n$. This paper will survey on various results and applications, in particular to the study of Rankin invariants of lattices. We also give some bounds for the size of designs and codes which were obtained in collaboration with E. Bannai.

1. INTRODUCTION.

This a survey on recent work with C. Bachoc, E. Bannai and G. Nebe. To start with, let us recall the classical notions of spherical designs and codes (see [5]). We endow the sphere $S^{n-1}$ with its canonical $O(n)$-invariant measure $dx$, normalized so as $\int_{S^{n-1}} dx = 1$.

Definition 1.1. A finite subset set $X$ of $S^{n-1}$ is a $t$-design, $t$ a positive integer, if for any homogeneous polynomial $f$ of degree at most $t$ one has

$$\int_{S^{n-1}} f(x) dx = \frac{1}{|X|} \sum_{x \in X} f(x)$$

Definition 1.2. A finite subset set $X$ of $S^{n-1}$ is an $s$-code, $s$ a positive integer, if the scalar products of pairwise distinct vectors in $X$ take at most $s$ values

$$|\{x \cdot y, x \neq y \in X\}| \leq s$$

Examples of designs arise in the theory of Euclidean lattices: if $L$ is a lattice in $\mathbb{R}^n$, i.e. a discrete subgroup of $\mathbb{R}^n$ of maximal rank, one defines the set $S(L)$ of minimal vectors of $L$ as the (finite) set of nonzero vectors in $L$ with minimal length. One can of course view $S(L)$, conveniently rescaled, as a finite subset of $S^{n-1}$. The following theorem, due to B. Venkov, is one of the motivation for our work on generalized designs:

Theorem 1.3 ([11]). If $S(L)$ is a 4-design, then $L$ achieves a local maximum of the Hermite function $\gamma(L) = \frac{\min L}{(\det L)^{1/n}}$

Recall that $\min L$ stands for the minimal squared length of nonzero vectors in $L$, and $\det L = vol(\mathbb{R}^n/L)^2$, so that $\gamma(L)^{n/2}$ is proportional to the density of the sphere packing associated to $L$. 
Our definition of designs in general Grassmanian spaces give rise to similar results for higher dimensional analogues of the Hermite invariants, the so-called Rankin invariants ([10]), see section 5.

It is natural to ask for a lower (resp. upper) bound for the size of a $t$-design (resp. $s$-code). Such bounds were exhibited in [5], and the notion of tight-design and code (i.e. achieving these bounds) was introduced. Moreover, a kind of duality between tight-designs and tight-codes was brought to the fore. In section 6, we give similar bounds for designs and codes in general Grassmanian spaces.

2. GRASSMANNNANS.

The Grassmannian space $\mathcal{G}_{m,n}$ (resp. $\mathcal{G}_{m,n}^{o}$) is the set of $m$-dimensional subspaces (resp. oriented subspaces) of $\mathbb{R}^{n}$. They are homogeneous spaces isomorphic respectively to $O(n)/O(m) \times O(n-m)$ and $O(n)/SO(m) \times O(n-m)$, and $\mathcal{G}_{m,n}^{o}$ is a 2 to 1 covering of $\mathcal{G}_{m,n}$. 

\[
\mathcal{G}_{m,n}^{o} \simeq O(n)/SO(m) \times O(n-m) \quad (2:1)
\]

EXAMPLE: $m = 1$

\[
\mathcal{G}_{1,n}^{o} = S^{n-1}
\]

\[
(2:1)
\]

\[
\mathcal{G}_{1,n} = \mathbb{P}^{n-1}
\]

We need to characterize the relative positions of two $m$-dimensional subspaces of $\mathbb{R}^{n}$, or, in more sophisticated words, to characterize the $O(n)$-orbit of a couple $(p, q) \in \mathcal{G}_{m,n}$.

If $m = 1$, the relative positions of two lines through 0 is determined by their angle. In general, we define a $m$-tuple of principal angles as follows: we fix a base point $p_{0}$, for instance $p_{0} :=$ the $m$-dimensional subspace generated by the first $m$ vectors of the canonical basis of $\mathbb{R}^{n}$. Then, each couple $(p, q) \in \mathcal{G}_{m,n}$ can be written as $(p, q) = (g.p_{0}, h.p_{0})$ for suitable $g$ and $h$ in $O(n)$. We decompose the matrix $g^{-1}h$ into blocks

\[
g^{-1}h = \begin{pmatrix} A & B \\ C & D \end{pmatrix}
\]

with $A \in M_{m}(\mathbb{R})$, and denote by $1 \geq y_{1} \geq y_{2} \geq \cdots \geq y_{m} \geq 0$ the eigenvalues of the real symmetric matrix $AA^{t}$. Finally, we let $t_{i} := \sqrt{y_{i}} = \cos \theta_{i} \in [0,1]$. Then, the $O(n)$-orbit of $(p, q)$ is characterized by the $m$-tuple $(t_{1}, \cdots , t_{m})$

(3) $O(n).(p, q) \leftrightarrow (t_{1}, \cdots , t_{m})$.

REMARK. it is readily seen that this definition of the principal angles is equivalent to the classical one, as given in [7], p.584, for instance.
As for the $O(n)$-orbit of a couple $(\tilde{p}, \tilde{q}) \in \mathcal{G}_{m,n}^{o}$, one needs one more invariant, namely $\epsilon := \frac{\det A}{|\det \Lambda|}$:

$$O(n).(\tilde{p}, \tilde{q}) \leftrightarrow (\epsilon, t_1, \cdots, t_m).$$

3. SOME HARMONIC ANALYSIS. ZONAL FUNCTIONS.

The space of square integrable functions on $\mathcal{G}_{m,n}$, resp $\mathcal{G}_{m,n}^{o}$ splits into $O(n)$-irreducible modules $H_{m,n}^{\mu}$, indexed by partitions $\mu = \mu_1 \geq \cdots \geq \mu_m$ of an integer $k$ in at most $m$ nonzero parts, as follows (see [8] p. 546 or [2]): we say that a partition $\mu = \mu_1 \geq \cdots \geq \mu_m \geq 0$ is admissible if

$$\mu_i \equiv \mu_j \mod 2 \text{ for all } (i, j),$$

and that $\mu$ is even (resp. odd), if its components are even (resp. odd). The integer $k = \sum \mu_i$, denoted by $|\mu|$, is the degree of $\mu$. We have:

$$L^2(\mathcal{G}_{m,n}^{o}) = \bigoplus_{\mu \text{ admissible}} H_{m,n}^{\mu}$$

$$L^2(\mathcal{G}_{m,n}) = \bigoplus_{\mu \text{ and even admissible}} H_{m,n}^{\mu}$$

EXAMPLE: $m = 1$, $\mu = k$, $H_{1,n}^{k} = \text{Harm}_k[X_1, \cdots, X_n]$, the space of harmonic polynomials of degree $k$.

It is worth noticing that the $H_{m,n}^{\mu}$ do depend only on $n$ and $\mu$, that is to say, if $m \leq m'$ and $\mu$ is a partition with at most $m$ nonzero parts, then $H_{m,n}^{\mu} \simeq H_{m',n}^{\mu}$.

To each irreducible constituent $H_{m,n}^{\mu}$ is attached a zonal function $P_{\mu}$ on $\mathcal{G}_{m,n}^{o} \times \mathcal{G}_{m,n}^{o}$, characterized by:

(i) $P_{\mu}(p, .) \in H_{m,n}^{\mu}$ for all $p \in \mathcal{G}_{m,n}^{o}$, $P_{\mu}(., q) \in H_{m,n}^{\mu}$ for all $q \in \mathcal{G}_{m,n}^{o}$

(ii) $P_{\mu}(\sigma p, \sigma q) = P_{\mu}(p, q)$ for all $\sigma \in O(n)$, $(p, q) \in \mathcal{G}_{m,n}^{o}$

If $\mu$ is even, one has

$$P_{\mu}(p, q) = p_{\mu}(y_1(p, q), \cdots, y_m(p, q)),$$

where $p_{\mu}(Y_1, \cdots, Y_m)$ is a symmetric polynomial of degree $\frac{|\mu|}{2}$, whereas if $\mu$ is odd

$$P_{\mu}(p, q) = (\epsilon t_1 \cdots t_m) p_{\mu}(y_1, \cdots, y_m),$$

with $p_{\mu}(Y_1, \cdots, Y_m)$ a symmetric polynomial of degree $\frac{|\mu| - m}{2}$.

From now on, we normalize the zonal functions so as:

$$P_{\mu}(p, p) = 1.$$
(ii) $P_{\lambda}P_{\mu} = \sum_{\tau} c_{\lambda,\mu}(\tau)P_{\tau}$, with $c_{\lambda,\mu}(\tau) \geq 0$.

For any integer $k \geq 1$, we define

$$H_{k}^{+} := \bigoplus_{\mu \leq k \text{ even}} H_{m,n}^{\mu} \subset L^{2}(G_{m,n}) \subset L^{2}(G_{m,n}^0)$$

and

$$H_{k}^{-} := \bigoplus_{\mu \leq k \text{ odd}} H_{m,n}^{\mu} \subset L^{2}(G_{m,n})^\perp \subset L^{2}(G_{m,n}^0).$$

**Definition 4.1** ([2]). A subset $D \subset G_{m,n}$ is a $2k$-design if

$$\forall \varphi \in H_{2k}^{+}, \int_{G_{m,n}} \varphi(p)dp = \frac{1}{|D|} \sum_{p \in D} \varphi(p)$$

Notice that, since the definition is given in the setting of non oriented grassmannians, what we get for $m = 1$ is not exactly the definition of spherical designs, but more restrictively, the notion of antipodal design (see [5]).

There are several criteria to test whether a given subset of a Grassmannian space is a design. The first one involves the zonal functions $P_{\mu}$ mentioned above.

**Proposition 4.2** ([2]). The following properties, for a subset $D \subset G_{m,n}$, are equivalent:

(i) $D$ is a $2k$-design.
(ii) $\forall \mu$ with $2 \leq |\mu| \leq 2k$, $\sum_{p \in D} P_{\mu}(p, \cdot) = 0$.
(iii) $\forall \mu$ with $2 \leq |\mu| \leq 2k$, $\sum_{(p,q) \in D^2} P_{\mu}(p, q) = 0$.

In order to apply this proposition, one has to compute explicitly the polynomials $P_{\mu}$. This is done in [9]. For $m = 1$, the $P_{\mu}$ are the classical Gegenbauer polynomials [5].

We also have criteria of a completely different kind, involving group theory. The orthogonal group $O(n)$ acts on the set of $n$ symmetric matrices $SM_{n}$ by $g.S = (g^{t})^{-1}Sg^{-1}$, which in turn induces a representation of $O(n)$ in $\text{Hom}_{k}(SM_{n})$, the space of homogeneous polynomials of degree $k$ in the matrix argument $S = (S_{i,j}) \in SM_{n}$

$$g.P(S) := P(g^{-1}.S) = P(g^{t}Sg).$$

We then have the following theorem:

**Theorem 4.3** ([2]). Let $G$ be a finite subgroup of $O(n)$. Then, the following properties are equivalent:

(i) $\forall m \leq \frac{n}{2}, \forall p \in G_{m,n}, G \cdot p$ is a $2k$-design.
(ii) $\text{Hom}_{k}(SM_{n})^{G} = \text{Hom}_{k}(SM_{n})^{O(n)}$. 

We then have the following theorem:
This applies in particular when $G = \text{Aut} L$ is the automorphism group of a lattice $L$. For instance, if $L = \mathbb{D}_4, \mathbb{E}_6$ or $\mathbb{E}_7$, theorem (4.3) applies with $k = 2$. If $L = \mathbb{E}_8$, it applies with $k = 3$, and if $L = \Lambda_{24}$ (the Leech lattice), with $k = 5$ (see [2]).

5. Rankin invariants.

Besides the classical Hermite function $\gamma (= \gamma_1$ in what follows), which we mentioned in the introduction, Rankin [10] defined a collection of functions $\gamma_m$, in the following way: let $L$ be a lattice in $\mathbb{R}^n$, endowed with the usual scalar product denoted $x \cdot y$, and $1 \leq m \leq \dim L$ an integer. One defines

\begin{equation}
\delta_m(L) = \inf_{p \in L(m)} \det p,
\end{equation}

in which $L(m)$ stands for the set of $m$-dimensional sublattices of $L$, and

\begin{equation}
\gamma_m(L) = \delta_m(L)/(\det L)^{\frac{m}{n}}
\end{equation}

For $m = 1$, $\gamma_1(L)$ is the classical Hermite invariant of $L$. In general, the function $\gamma_m$ is bounded on the set of $n$-dimensional positive definite lattices ([10]), and the supremum, which actually is a maximum, is denoted by $\gamma_{m,n}$. The lattices achieving a local maximum for $\gamma_m$ are called $m$-extreme (see [4] for a characterization of $m$-extreme lattices in terms of $m$-perfection and $m$-eutaxy).

We define the set of minimal $m$-sections of $L$ as

\begin{equation}
S_m(L) = \{ p \in L(m) \mid \det p = \delta_m(L) \}
\end{equation}

which is a finite set. The map $p \mapsto \mathbb{R}p$ (the $m$-dimensional subspace spanned by $p$) induces an embedding of $S_m(L)$ in $\mathcal{G}_{m,n}$ (this is because $\mathbb{R}p/p$ is torsion-free, by the minimality of $p$). So, we can view $S_m(L)$ as a subset of $\mathcal{G}_{m,n}$. We then have the following theorem, analogous to Venkov's theorem mentioned in the introduction:

**Theorem 5.1** ([2]). $S_m(L)$ is a 4-design $\Rightarrow L$ is $m$-extreme.

The proof relies on the characterization of $m$-extreme lattices in terms of $m$-perfection and $m$-eutaxy mentioned above. This theorem, together with theorem 4.3, allows to check that some classical lattices are extreme with respect to all Rankin invariants:

**Proposition 5.2.** If $L = \mathbb{D}_4, \mathbb{E}_6, \mathbb{E}_7, \mathbb{E}_8$ or $\Lambda_{24}$, then $L$ is $m$-extreme for any $m$, $1 \leq m \leq \frac{\dim L}{2}$.

This kind of results would be out of reach without the help of theorem 4.3 and 5.1.
Definition 6.1 ([1]). Let \( f(Y_1, \cdots, Y_m) \) be a symmetric polynomial such that \( f(1, \cdots, 1) = 1 \).

A subset \( D \subset G_{m,n} \) is an \( f \)-code if for all \( (p, q) \in D^2, p \neq q \) one has
\[
f(y_1(p, q), \cdots, y_m(p, q)) = 0.
\]

REMARK. For \( m = 1 \), one recovers the usual definition of an \( s \)-code, i.e. a set of points on the sphere such that the mutual distances take at most \( s \) distinct values.

Let \( d_k^+ = \dim H_k^+ \) and \( d_k^- = \dim H_k^- \). These dimensions can be easily calculated from the dimensions \( d_n^\mu \) of the irreducible components \( H_m,n^\mu \), as given for instance in [6], chapter 24. They are involved in the following two theorems, which give bounds for the size of designs and codes in \( G_{m,n} \).

Theorem 6.2 ([1]). Let \( D \subset G_{m,n} \) be a \( 2k \)-design. Then
\[
|D| \geq \max(d_k^+, d_k^-).
\]
If equality holds, then \( D \) is an \( f \)-code with respect to
\[
f = \frac{1}{d_k^+} \sum_{\mu \text{ even}, |\mu| \leq k} d_\mu p_\mu \quad \text{or} \quad y_1 \cdots y_m \sum_{\mu \text{ odd}, |\mu| \leq k} \frac{d_\mu p_\mu}{d_k^-}.
\]

\( (d_k^+ > d_k^-) \quad \text{or} \quad (d_k^- > d_k^+) \)

Definition 6.3 ([1]). An \( f \)-code has type 1 if \( Y_1 \cdots Y_m \) divides \( f \), type 0 otherwise.

Theorem 6.4 ([1]). Any \( f \)-code \( D \subset G_{m,n} \) satisfies
\[
|D| \leq d_k^+, \quad \text{where} \quad k = 2 \deg f.
\]
If moreover \( f \) has type 1, then \( D \subset G_{m,n} \) satisfies
\[
|D| \leq d_k^-,
\]
where \( k = 2 \deg f - m \).

If equality holds, then
\[
f = \frac{1}{d_k^+} \sum_{\mu \text{ even}, |\mu| \leq k} d_\mu p_\mu \quad \text{(type 0)},
\]
resp.
\[
f = \frac{y_1 \cdots y_m}{d_k^-} \sum_{\mu \text{ odd}, |\mu| \leq k} d_\mu p_\mu \quad \text{(type 1)}
\]
and \( D \) is a \( 2k \)-design.

Designs, resp. codes, achieving the bound of theorem 6.2, resp. 6.4, are called tight.

EXAMPLE. In [3], §5, an infinite family \( D_p \) of packings in \( G_{\frac{n-1}{2},p} \), \( p \) a prime which is either 3 or congruent to \(-1\) modulo 8, is defined. It consists
ON A GENERALISATION OF SPHERICAL CODES AND DESIGNS.

on $\frac{p(p+1)}{2} = d_{[0,\ldots,0]} + d_{[2,0,\ldots,0]} = d_{2}^{+}$ subspaces with same pairwise chordal distance $d^2 = \frac{(p+1)^2}{1(p+2)}$. Since $d^2 = \sum \sin^2 \theta_i = \frac{p-1}{2} - \sum y_i$, $D_p$ is an f-code, with $f = \frac{(p+2)(\sum y_i)-(p^2-5)}{p^2-5}$, and theorem 6.4 applies, so that:

**Proposition 6.5 ([1]).** For any prime $p$ which is either 3 or congruent to $-1$ modulo 8, $D_p$ is a tight 4-design in $G_{\frac{p-1}{2},p}$.
