1 Introduction

The question concerning applicative theories and computational complexity was posed by S. Feferman [11]. Namely he asked whether a program similar to Buss' bounded arithmetic [4] can be carried through in the context of applicative theories or explicit mathematics.

This question was answered by T. Strahm [16], [17], [18]. He first presented the theory PTO which can be viewed as an applicative analogue of Cook's $PV$ or alternatively Ferreira's PTCA [12]. Then he went on to define another theory $PT$ which has notation induction axiom for NP formulae. Strahm proved that the theory $PT$ is related to type 1 and type 2 poly-time functionals. However it is still open whether provably total terms of $PT$ of arbitrary type can be witnessed by poly-time computations.

In this paper we will deal with applicative theory for the constant depth circuit class $AC^0$. In [13] the author presented an applicative theory $CDD$ whose probably total functions are exactly those in $AC^0$. There we deal only with type 1 functions and here we will prove that provably total type 2 functionals of $CDD$ is witnessed by type 2 $AC^0$ functions in the sense of Clote et.al. [8].

Let us now state the construction of the paper. In the next section we will present basic definitions. In section 3 we will prove that the provably total type 2 functionals of $CDD$ can be realized by type 2 $AC^0$ functions. In section 4 we will present some questions concerning applicative theories and boolean circuit computation.

2 Basic definitions

In this section we will give basic definitions of our theories. We will introduce our base theory for binary words. The language $\mathcal{L}_{CDO}$ is a first order language with individual variables $a, b, c, \ldots, x, y, z, \ldots$ possibly with subscripts. We also have individual constants $\mathrm{K}, \mathrm{S}$ (combinators), $\mathrm{P}, \mathrm{P}_0, \mathrm{P}_1$ (pairing and unpairings), $\mathrm{D}$ (definition by cases on binary words), $\varepsilon$ (empty word) $0, 1$ (zero, one),
$C_{\subseteq}$ (initial subword relation), $l_w$ (tally length of binary word), $\ast, \times$ (word concatenation and word multiplication), LD, MSP (and most significant part and the least digit), CR (concatenation recursion on notation operation). $L_{CDO}$ has a function symbol $\cdot$ (term application) and relation symbols $\downarrow$ (defined), $W$ (binary words) and $=$ (equality). The language $L_{CDD}$ is obtained from $L_{CDO}$ by removing the CRN operator CR.

Terms are built up from variables and constants by using term application, that is, all variables and constants are terms and if $s, t$ are terms then $s \cdot t$ is also a term. Formulae are built up from atomic formulae using logical symbols $\land, \lor, \supset, \forall$ and $\exists$. We assume that the negation symbol $\neg$ is not in our language but defined as $\neg A \equiv (A \supset K = S)$. Quantifiers of the form $\forall x \in W$ and $\exists x \in W$ are called $W$-bounded and their intended meanings are

$$\forall x \in WA(x) \equiv \forall x(x \in W \supset A(x)),$$
$$\exists x \in WA(x) \equiv \exists x(x \in W \land A(x))$$

respectively. Furthermore, quantifiers of the form $\forall x \subseteq t$ and $\exists x \subseteq t$ are called sharply bounded and their intended meanings are

$$\forall x \subseteq tA(x) \equiv \forall x(x \subseteq t \supset A(x)),$$
$$\exists x \subseteq tA(x) \equiv \exists x(x \subseteq t \land A(x))$$

respectively. A formula is called $W$-free if it does not contain the predicate symbol $W$. A formula is called semi-positive if for all subformula of the form $A \subset B$, $A$ is an atomic formula. Some extra symbols which are not included in the language are used for convenience. First we write $s \subseteq t$ instead of $C_{\subseteq}$. Also $\ast$ and $\times$ are presented in infix notation as $s \ast t$ and $s \times t$ and we write $x0$ and $x1$ for $x \ast 0$ and $x \ast 1$ respectively.

Since our theories are concerned with partial term application, a term is not necessarily to be totally defined. So we introduce the partial equality relation as

$$s \simeq t \equiv (s \downarrow \lor t \downarrow) \supset (s = t).$$

Furthermore, we will use the following abbreviations in the sequel:

$$\bar{s} \in W \equiv W(s_1) \lor \cdots \lor W(s_n),$$
$$t : W \rightarrow W \equiv (\forall x \in W)(tx \in W),$$
$$t : W^{n+1} \rightarrow W \equiv (\forall x \in W)(tx : W^n \rightarrow W).$$

The theory $BOW$ (Base Theory for binary Words) is a $L_{CDO}$ theory which consists of the following axioms:

I Partial combinatory algebra

1. $Kxy \simeq x$
2. $Sxy \downarrow \land Sxyz \simeq xz(yz)$

II Pairing and unpairings
III Binary word manipulation on $W$

(4) $\epsilon \in W \land 0 \in W \land 1 \in W$

(5) $*: W^2 \rightarrow W$

(6) $x \in W \supset x \ast \epsilon = x$

(7) $x \in W \land y \in W \supset x \ast (y \ast i) = (x \ast y) \ast i \quad (i = 0, 1)$

(8) $x \in W \land y \in W \supset x \ast 0 \neq y \ast 1 \land x \ast 0 \neq \epsilon \land x \ast 1 \neq \epsilon$

(9) $x \in W \land y \in W \land x \ast 0 = y \ast 0 \supset x = y$

(10) $x \in W \land y \in W \land x \ast 1 = y \ast 1 \supset x = y$

IV Word multiplication on $W$

(11) $\times: W^2 \rightarrow W$

(12) $x \in W \supset x \times \epsilon = \epsilon$

(13) $x \in W \land y \in W \supset (x \times (y \ast 0)) = (x \times y) \ast x \land x \times (y \ast 1) = (x \times y) \ast x$

V Predecessor on $W$

(14) $\text{PR}: W \rightarrow W$

(15) $\text{PR}\epsilon = \epsilon$

(16) $x \in W \supset \text{PR}(x \ast 0) = \text{PR}(x \ast 1) = x$

(17) $x \in W \land x \neq \epsilon \supset (\text{PR}x) \ast 0 = x \lor (\text{PR}x) \ast 1 = x$

VI Initial subword relation on $W$

(18) $x \in W \land y \in W \supset x \subseteq y \lor x \not\subseteq y$

(19) $x \in W \supset (x \subseteq \epsilon \iff x = \epsilon)$

(20) $x \in W \land y \in W \land y \neq \epsilon \supset (x \subseteq y \iff x \subseteq \text{PR} y \lor x = y)$

VII Tally length of binary words

(21) $1_w : W \rightarrow W \land 1_w \epsilon = \epsilon$

(22) $x \in W \rightarrow 1_w(x \ast 0) = (1_w x) \ast 1 \land 1_w(x \ast 1) = (1_w x) \ast 1$

VIII Most significant part and least digit

(23) $x \in W \supset \text{MSP} x \epsilon = x$

(24) $x \in W \land y \in W \supset \text{MSP} x (y 0) = \text{PR}(\text{MSP} xy) \land \text{MSP} x (y 1) = \text{PR}(\text{MSP} xy)$

(25) $\text{LD}\epsilon = \epsilon$

(26) $x \in W \supset \text{LD} x 0 = 0 \land \text{LD} x 1 = 1$

IX Definition by cases on $W$
\[ \text{(27)} \quad a \in W \land b \in W \land a = b \supset Dxyab = x \]
\[ \text{(28)} \quad a \in W \land b \in W \land a \neq b \supset Dxyab = y \]

The semantics for our theories are given using the well-known equivalence between combinatory logic with extensionality and \( \lambda \eta \) (see Troelstra and van Dalen [19] for details). The open term model \( \mathcal{M}(\lambda \eta) \) is based on \( \lambda \eta \) reduction of the untyped lambda calculus and one simply extends \( \lambda \eta \) reduction with the obvious clauses for the new constants. The universe of \( \mathcal{M}(\lambda \eta) \) is the set of all terms. The equality \( = \) is reduction to a common reduct and \( W \) is interpreted as the set of all terms \( t \) so that \( t \) reduces to a standard binary word. The set of all binary words is denoted by \( W \). Finally the application \( s \cdot t \) is simply the term \( ts \). As usual \( \mathcal{M}(\lambda \eta) \models A \) if \( A \) is valid in the model \( \mathcal{M}(\lambda \eta) \) for any formula \( A \). set of all terms.

3 Theories for circuit complexity

We now state some results relating weak applicative theories and boolean circuit complexity classes. First we will give some additional axioms which are used to form applicative systems for constant depth circuit class \( AC^0 \).

Concatenation recursion on notation

\[ \text{(29)} \quad f : W \rightarrow W \land g \in P(W^2) \supset CRfg : W^2 \rightarrow W \]
\[ \text{(30)} \quad f : W \rightarrow W \land g \in P(W^2) \land x \in W \land y \in W \land y \neq \epsilon \land \land h = CRfg \]
\[ \supset hx = fx \land hxy = hx(PRy) \ast gx(PRy) \]

Set induction on \( W \)

\[ \text{(31)} \quad f \in P(W) \land f \epsilon = 0 \land (\forall x \in W)(f(PRx) = 0 \supset fx = 0) \]
\[ \supset (\forall x \in W)(fx = 0) \]

The system \( CDD \) is a \( \mathcal{L}_{CDD} \) theory whose axioms are (1) to (28) of \( CDO \) extended by the following axioms:

Notation induction on \( W \) for open \( W \)-free semi-positive \( \mathcal{L}_{CDD} \) formulae

\[ \text{(32)} \quad A(\epsilon) \land \forall x \in W(A(PRx) \supset A(x)) \supset (\forall x \in W)A(x), \]
where \( A \) is an open \( W \)-free and semi-positive formula.

Bit comprehension for open \( W \)-free semi-positive \( \mathcal{L}_{CDD} \) formulae

\[ \text{(33)} \quad (\forall \bar{x} \in W)(\exists z \in W)(wz < w(f \bar{x}) \land (\forall y \subseteq f \bar{x})(A(\bar{x}, y, f) \leftrightarrow BIT_{xy} = 1)). \]
where \( BIT_{xy} = LD(MSP_{xy}) \) and \( A \) is an open \( W \)-free and semi-positive formula.
As usual $AC^0$ is the class of functions computable by $U_{E}^{*}$-uniform circuit family of constant depth and polynomial size. For the precise definitions of these notions, see [?]. In [13] the author showed that the probably total first order terms of $CDO$ and $CDD$ are exactly functions in $AC^0$. More precisely,

**Definition 1** A function $F : \mathbb{W} \rightarrow \mathbb{W}$ is provably total in a theory $T$ if there exists a term $t_F$ in the language of the theory in concern such that

1. $T \vdash t_F : W^n \rightarrow W$ and
2. $T \vdash t_F \overline{w}_1 \cdots \overline{w}_n = F(w_1, \ldots , w_n)$ for all $w_1, \ldots , w_n \in \mathbb{W}$.

**Theorem 1 (Kuroda [13])** A function is provably total in $CDD$ or $CDT$ if and only if it is computable by $AC^0$ functions.

By extending the method in [13] we can show that the provably total type 2 functionals of $CDT$ are type 2 $AC^0$ functionals. First we will clarify what is meant by type 2 $AC^0$ functionals.

Let $\mathbb{W}^\mathbb{W}$ be the set of type 1 functions, that is, a mapping from $\mathbb{W}$ to $\mathbb{W}$. A type 2 functional of rank $(k, l)$ is a mapping from $(\mathbb{W}^\mathbb{W})^k \times \mathbb{W}^l$ to $\mathbb{W}$. We denote type 2 functionals by upper case letters $F, G, \ldots$ and so on. Let $Ap$ be a type 2 functional defined by $Ap(f, x) = f(x)$ for all $f, x$.

**Definition 2** A functional $F$ is defined by functional composition from $G, H_1, \ldots , H_n$ if

$$F(\vec{f}, \vec{x}) = G(\vec{f}, H_1(\vec{f}, \vec{x}), \ldots , H_n(\vec{f}, \vec{x}))$$

for all $\vec{f}, \vec{x}$.

**Definition 3** A functional $F$ is defined by expansion from $G$ if

$$F(\vec{f}, \vec{g}, \vec{x}, \vec{y}) = G(\vec{f}, \vec{x})$$

for all $\vec{f}, \vec{g}, \vec{x}, \vec{y}$.

**Definition 4** A functional $F$ is defined by concatenation recursion on notation (CRN) from $G, H_0$ and $H_1$ if

$$F(\vec{f}, \vec{x}, \varepsilon) = G(\vec{f}, \vec{x})$$
$$F(\vec{f}, \vec{x}, y \ast i) = F_i(\vec{f}, \vec{x}, y) \ast H_i(\vec{f}, \vec{x}, y) \quad i = 0, 1$$

provided $H_i(\vec{f}, \vec{x}) \leq 1$ for all $\vec{f}, \vec{x}$.

**Definition 5** The class $F_2AC^0$ of type 2 functionals is the smallest class of functions containing 0 (zero function), $s_0, s_1$ (successors on binary words), $P_k^n$ (projection), $x \# y = 2^{\mid x \mid \cdot \mid y \mid}$, $Ap$ and closed under functional composition, expansion and concatenation recursion on notation operations.
Theorem 2 (Clote, Kapron, Ignjatovic [8]) A functional $F(\bar{f}, \bar{x})$ belongs to $F_2AC^0$ if and only if it is computable by a $U^*_E$-uniform circuit family with constant depth and $P(|\bar{f}|, |\bar{x}|)$ size for some polynomial $P$.

Now we will extend the realizability theorem for CDD to type 2 functionals. In [13] we defined the realizability relation for semi-positive formulae. Here we will extend this so that it can manipulate type 2 case. First we must clarify what it means for a type 2 functional to be definable in the structure $\mathcal{M}$. Let $W^W$ denote the set of all individuals $f$ in the universe $|\mathcal{M}|$ such that $f : \mathcal{M} \to \mathcal{M}$ is true in $\mathcal{M}$. Denote by $\bar{f}$ the function $W \to W$ which is defined by $f$ in $\mathcal{M}$.

Definition 6 A type 2 functional $F$ of rank $(k, l)$ is definable in $\mathcal{M}$ if there exists a closed term $t_F$ such

$$\mathcal{M} \models t_F f_1 \cdots f_k \bar{w}_1 \cdots \bar{w}_l = F(\bar{f}_1, \ldots, \bar{f}_k, w_1, \ldots, w_l)$$

for all $f_1, \ldots, f_k \in W^W$ and $w_1, \ldots, w_l \in W$.

We also define the provably totality of type 2 functionals in a given applicative system. We use the following abbreviation:

$$t : (W^W)^k \times W^l \to W \equiv (\forall \bar{f} : W \to W)(\forall \bar{w} \in W)t \bar{f} \bar{w} \in W.$$ 

Definition 7 A type 2 functional $F$ of rank $(k, l)$ is provably total in a theory $T$ if there exists a closed term $t_F$ in the language of $T$ such that

1. $T \vdash t : (W^W)^k \times W^l \to W$, and

2. $t_F$ defines $F$ in the open term model $\mathcal{M}(\lambda \eta)$.

Now let us extend the realizability for CDD in [13] to type 2 functionals using the method by Strahm [18]. Let $\mathcal{SP}$ denote the set of semi-positive formulae. A formula is in the class $\mathcal{C}_0$ if either $A$ is in $\mathcal{SP}$ or $A$ is of the form $(B \supset C)$ or $(\forall x)(B \supset C)$ for some $B, C \in \mathcal{SP}$. Then cut elimination for CDD implies the following:

Theorem 3 Let $\Gamma \to \Delta$ be a sequent where $\Gamma$ and $\Delta$ consists of $\mathcal{C}_0$ and $\mathcal{SP}$ formulae respectively. Suppose that $\text{CDD} \vdash \Gamma \to \Delta$. Then there exists a CDD-proof of $\Gamma \to \Delta$ whose sequents consists of $\mathcal{C}_0$ formula in the antecedent and $\mathcal{SP}$ formulae in the succedent.

Next we will define the realizability relation for $\mathcal{C}_0$ formulae. For formulae in $\mathcal{SP}$ the set $\mathcal{R}$ of realizers is defined inductively as

1. if $\alpha$ is a binary string then $\alpha \in \mathcal{R}$ and

2. if $\alpha, \beta \in \mathcal{R}$ then $\langle \alpha, \beta \rangle \in \mathcal{R}$

where $\langle \cdot, \cdot \rangle$ is a pairing function.
**Definition 8** For $\rho \in \mathcal{R}$ and a formula $A$ in $\text{csp}$, the realizability relation $\rho \triangleright A$ (read "$\rho$ realizes $A$") is defined inductively as follows:

- For a $W$-free atomic formula $A \triangleright t = s \iff \rho$ is any binary string and $\mathcal{M}(\lambda \eta) \models t$.  
- $\rho \triangleright t \in W_i \iff \mathcal{M}(\lambda \eta) \models t = \rho$ for some binary string $\rho$.  
- $\rho \triangleright A \lor B \iff \rho = \langle i, \rho_0 \rangle$ and either $i = 0$ and $\rho_0 \triangleright A$ or $i = 1$ and $\rho_0 \triangleright B$.  
- $\rho \triangleright A \land B \iff \rho = \langle \rho_1, \rho_2 \rangle$ with $\rho_1 \triangleright A$ and $\rho_2 \triangleright B$.  
- $\rho \triangleright (\forall x)A \iff \rho \triangleright A[x := a]$ where $a$ is not free in $A$.  
- $\rho \triangleright (\exists x)A \iff \rho \triangleright A[x := t]$ for some term $t$ which is not free for $x$ in $A$.  
- $\rho \triangleright (\forall x \subseteq t)A(x) \iff \rho = \langle \rho_e, \ldots, \rho_t \rangle$ where each element $\rho_a$ of $\rho$ corresponds to a with $\epsilon \subseteq a \subseteq t$ and $\rho_a \triangleright A(a)$.  

The crucial part is the case for formulae in $C_0 \setminus SP$. Realizers $\Theta, \Phi, \Psi, \ldots$ for formulae in $C_0 \setminus SP$ are functions from $W$ to $W$. For $A, B \in SP$ define

- $\Theta \triangleright (A \supset B) \iff$ if $\rho \triangleright A$ then $\Theta(\rho) \triangleright B$ for all $\rho$,  
- $\Theta \triangleright (\forall x)(A(x) \supset B(x)) \iff \Theta \triangleright (A(t) \supset B(t))$ for all term $t$.

Let $\Gamma$ be a finite sequence of formulae $A_1, \ldots, A_m, B_1, \ldots, B_n$ where $A_i \in SP$ for each $1 \leq i \leq m$ and $B_j \in C_0 \setminus SP$ for each $1 \leq j \leq n$. Let $\bar{\Theta} = \Theta_1, \ldots, \Theta_m$ be functions from $\mathcal{M}$ to $\mathcal{M}$ and $\bar{\rho} = \rho_1, \ldots, \rho_n \in \mathcal{R}$. Then $\bar{\Theta}, \bar{\rho} \triangleright \Gamma$ if $\Theta_i \triangleright A_i$ for $1 \leq i \leq m$ and $\rho_j \triangleright B_j$ for $1 \leq j \leq n$. Now we will state the main theorem;

**Theorem 4** Let $\Gamma \rightarrow \Delta$ be a sequent such that $\Gamma$ and $\Delta$ consists of $C_0$ and $SP$ formulae respectively. Suppose that $CDD \vdash \Gamma[s] \Rightarrow \Delta[s]$. Then there exists $F$ in $F_2AC^0$ such that for all terms $\bar{s}$ and all $\bar{\Theta}$ and $\bar{\rho}$, if $\bar{\Theta}, \bar{\rho} \triangleright \Gamma[\bar{s}]$ then for some $B$ in $\Delta[\bar{s}]$, $F(\bar{\Theta}, \bar{\rho}) \triangleright \Delta[\bar{s}]$.

**Corollary 1** Let $t$ be a closed term such that the sequent

$$f_1 : W \rightarrow W, \ldots, f_k : W \rightarrow W, x_1 \in W, \ldots, x_l \in W \Rightarrow tf_1 \cdots f_k x_1 \cdots x_l \in W$$

is provable in $CDD$. Then there exists type 2 functional $F$ in $F_2AC^0$ of rank $(k, l)$ such that $t$ defines $F$ in the open term model $\mathcal{M}(\lambda \eta)$.

## 4 Future research

In this section we give some questions concerning weak applicative theories and their connections with computational complexity theory.
4.1 Applicative theory for ALOGTIME

Find a right applicative theory whose provably total functions are exactly those in ALOGTIME. Some possible approaches are listed below:

1. Construct a theory based on Arai's AID [1] or Pitt's $T_1$ [14]. Note that the former does not refer to ALOGTIME functions but only to ALOGTIME predicates while the latter is a quantifier-free theory.

2. Another possibility is to use safe characterization of ALOGTIME as a recursion theoretical base of the theory. An applicative theory based on safe recursion is obtained by Cantini [5] for poly-time functions. In this formulation Cantini introduced two predicates for binary words, namely $W_0$ for safe binary words and $W_1$ for normal binary words. In [3], Bloch presented a safe characterization of ALOGTIME using very safe divide-and-conquer recursion

$$f(z, b, x; y) = \begin{cases} g(z, x; y) & \text{if } |z| \leq \max(b, 1) \\ h(z, x, y, f(Fh(z), b, x, y), f(Bh(z), b, x, y)) & \text{if } |z| > \max(b, 1) \end{cases}$$

So Cantini's formulation might be used to characterize ALOGTIME in the applicative context with a slight modification. Since the step function $h$ in very safe DCR contains no normal parameters, it follows that the definition tree of $h$ cannot contain recursion scheme. The difficulty lies in finding a corresponding restrictions on the proof system.

4.2 $Th - FO$ and CDD

Ferreira's string language theory $Th - FO$ [12] is another bounded arithmetic theory which corresponds to $AC^0$. This is based on the class $FO$ which consists of functions bitwise first order definable in finite structures. Let $Th - FO^\omega$ be a higher order analogue (define similarly as $PV^\omega$ of Cook and Urquhart). The main question here is whether there is a suitable interpretation from $Th - FO^\omega$ to CDD. Strahm [17] showed that this is true in the case of $PV^\omega$ and PT. The more important case is the converse, that is, is there a interpretation from CDD to $Th - FO^\omega$? The positive answer to this question implies that all higher order $AC^0$ functions are provably total in CDD.

It is worth mentioning that safe recursion is closely related to feasible higher type functionals, see [2],[15]. So Cantini's characterization might be useful in considering the provably defined higher type functionals of weak applicative theories.
