Kyoto University
A CORRELATION TECHNIQUE FOR PREDICTING THE VISCOSITY OF FREON-12 AND FREON-22 VAPOURS

BY M. SRIKHAN AND M. A. TIRUNARAYANAN

The paper presents correlations which fit the experimental viscosity data over a wide temperature and pressure range of Makita and a method for predicting the viscosity at any temperature and pressure of Freon-12 and Freon-22 vapours.

Introduction

The correlation of experimental viscosity data of Freon-12 (CCl₂F₂) vapour and Freon-22 (CHClF₂) vapour at a nominal pressure of one atmosphere has been presented by a number of investigators. The data have usually been represented by an equation of the form

\[ \mu = E \sqrt{T - F} \]

or

\[ \mu = E' \sqrt{T'} - F' \cdot \frac{T}{T'} \]

where \( E, F \) and \( E', F' \) are pressure dependent coefficients. However, there is need for predicting the viscosity at high pressures.

It may be realized from the experimental investigations of Makita, Benning and Markwood and Kamien and Witzell that viscosity data at high pressures are scarce and large gaps exist in the range of pressures investigated. It may be noted that Makita's experimental data for Freon-12 and Freon-22 vapours cover a wider range of pressures at constant temperatures than the data of Benning and Markwood or Kamien and Witzell.

Theory

The representation of experimental viscosity measurements by a viscosity-density relation greatly simplifies prediction of viscosity at the temperature and pressure conditions of practical interest. Since there is no generally acceptable method for the representation of experimental viscosity data of Freon vapour over a wide range of temperatures and pressures, the "excess viscosity" concept described by Iwasaki and Kestin may be extended to Freon-12 and Freon-22 vapours.

1) T. Makita, This Journal, 24, 74 (1954)
3) C. Z. Kamien and O. W. Witzell, ASHRAE TRANSACTIONS, 65, 663 (1959)
The excess viscosity defined as the difference between the viscosity, $\mu$, at a particular temperature and density and the viscosity, $\mu_0$, at the same temperature but at zero-density is a unique function of density of the form

$$\mu - \mu_0 = B\rho + C\rho^2,$$

where $\mu = \mu(\rho, T)$ and $\mu_0 = \mu(0, T)$.

The coefficients, $B$ and $C$, which depend on the nature of the vapour are only mildly varying functions of temperature.

Calculations and Correlations

The first step in the computational technique is to determine the zero-density values of viscosity from the experimental data on viscosity presented by Makita at temperatures 25, 50, 100, 150 and 200°C covering a wide range of pressures at each temperature. The viscosity at any temperature is plotted versus density and the data is correlated by the least square method using the expression

$$\mu = \mu_0 + b\rho + c\rho^2.$$

The zero-density values of viscosity, $\mu_0$, so obtained, as well as the coefficients, $b$ and $c$, are presented in Table 1. The standard deviation, $\sigma$, defined in standard texts on statistical methods is calculated

A Correlation Technique for Predicting the Viscosity

by the following equation

$$\sigma = \left[ \frac{1}{N} \sum_{i=1}^{N} (\mu_i - \overline{\mu})^2 \right]^{1/2}.$$  \hspace{1cm} (4)

The "greatest error" signifies the maximum difference between the experimental and correlated value of viscosity. The per cent greatest error is calculated on the basis of the experimental viscosity value.

![Graph 1: Variation of viscosity of Freon-12 vapour with density](image1)

![Graph 2: Variation of viscosity of Freon-22 vapour with density](image2)

Figs. 1 and 2 respectively show the variation of viscosity of Freon-12 and Freon-22 vapours with density.

Using the zero-density values of viscosity, \(\mu_0\), given in Table 1 and the experimental viscosity values of Makita, the excess viscosity, \((\mu - \mu_0)\), is plotted versus density at any temperature and pressure. For Freon-12 and Freon-22 vapours, it is found that the excess viscosity is a unique function of density. The plot of excess viscosity versus density is correlated using equation (2) by the least

square method. The values of $B$ and $C$, so obtained, are given in Table 2 with the standard deviation, $\sigma$, and the probable error, P. E., calculated by the equation

$$P. E. = 0.6745\sigma.$$ (5)

In Fig. 3, the excess viscosity of Freon-12 and Freon-22 vapours is plotted versus density.

**Zero-density viscosity of Freon-12 and Freon-22 vapours**

It is important to realize that the determination of viscosity at any temperature and density requires information regarding the temperature dependence of zero-density viscosity. The temperature dependence of zero-density viscosity may be represented by an equation of the form

$$\mu_0 = B_0 \sqrt{T} - C_0.$$ (6)

where the constants, $B_0$ and $C_0$, depend on the nature of the vapour.

The constants, $B_0$ and $C_0$, for Freon-12 and Freon-22 vapours are evaluated by matching equation (6) to the zero-density viscosity-temperature data presented in Table 1 using the method of least squares. The values of $B_0$ and $C_0$, so obtained, are given in Table 3. The standard deviation is calculated by equation (4) and the probable error by equation (5).

**Fig. 4** Zero-density viscosity of Freon-12 and Freon-22 vapours
In Fig. 4 is presented a plot of $\mu_0$ vs. $\sqrt{T}$ for Freon-12 and Freon-22 vapours.

**Results and Discussions**

It is evident from Tables 1, 2 and 3 that equations (2), (3) and (6) provide the best fit to the experimental data of Makita\(^1\) and the zero-density viscosity.

A plot of viscosity versus density of Freon-12 and Freon-22 vapours represented respectively in Figs. 1 and 2 signifies that the viscosity isotherms are parallel curves. The significance of this is that it greatly simplifies the measurement, as viscosity over wide range of temperatures and pressures may be predicted from the viscosity data at atmospheric pressure for wide range of temperatures and from the viscosity data at atmospheric temperature for wide range of pressures.

It can be seen in Fig. 3 that the excess viscosity-density data of Freon-12 and Freon-22 vapours are represented by a single curve for each vapour. The ability to predict excess viscosity from a single curve greatly simplifies the evaluation of viscosity from a knowledge of the zero-density viscosity and density.

Fig. 4 indicates a linear relationship between $\mu_0$ and $\sqrt{T}$. The zero-density viscosity, $\mu_0$, at any temperature of Freon-12 and Freon-22 vapours may, therefore, be satisfactorily determined by equation (6).

**Conclusion**

The present correlations facilitate design of engineering systems as viscosity information on Freon-12 and Freon-22 vapours may, readily, be obtained by equations (2) and (6) from a knowledge of density, $\rho$, coefficients, $B$, $C$, and constants, $B_0$, $C_0$. The density of Freon-12 vapour or Freon-22 vapour may be obtained from tables given in standard texts\(^7\). The coefficients, $B$, $C$, and constants, $B_0$, $C_0$, are to be taken from Tables 2 and 3 respectively.
