## Inverse semigroups and permutation properties

Kunitaka Shoji  
(庄司 邦孝)

Department of Mathematics, Shimane University

The purpose of this talk is to introduce a theorem on permutation properties of inverse semigroups, appearing in Okniński's book[2] and to give a comment on the proof of a lemma for the theorem.

**Definition.** A semigroup  $S$  has the permutation property  $\mathcal{B}_n$  if there exists an integer  $n \geq 2$  such that  $w_1 w_2 \dots w_n = w_{\sigma(1)} w_{\sigma(2)} \dots w_{\sigma(n)}$  for some  $\sigma \neq 1 \in S_n$ .

**Definition.** A ring  $R$  satisfies a polynomial identity  $p(x_1, x_2, \dots, x_n)$  if all coefficients of  $p(x_1, x_2, \dots, x_n)$  are  $\pm 1$  and  $p(r_1, r_2, \dots, r_n) = 0$  for all  $r_i \in R$ . In this case,  $R$  is called a *PI*-ring.

**Problem** [3, Restivo and Reutenauer].

Does the semigroup ring  $k[S]$  of a semigroup  $S$  have the permutation property satisfy a polynomial identity?

**Theorem** ([2, Theorem 23]). Let  $S$  be an inverse semigroup. Then the following are equivalent :

- (1)  $S$  is finitely generated and satisfies the permutation property.
- (2)  $S$  has finitely many idempotents, and all subgroups of  $S$  are finitely generated and abelian-by-finite.
- (3)  $K[S]$  is a left and right noetherian *PI*-algebra.

A proof of the theorem is based on Shirshov's results concerning combinatorics on words, Blyth's results concerning groups with the permutation property, and structure theorems in semigroup ring theory.

We shall give a semigroup theoretical proof of the following lemma used for the proof of the theorem above.

**Lemma** ([2, Lemma 22]). Let  $S$  be a finitely generated inverse semigroup. If  $S$  has the permutation property, then  $S$  has finitely many idempotents.

**Proof.** Let  $a \in S$ . Then the principal factor semigroup  $S_a = \mathcal{J}_a/I(a)$  is a 0-simple (or simple) semigroup (see [1]). By [2, Theorem 17],  $S_a$  is a completely 0-simple (or simple) semigroup. Here we assume that  $S$  has  $\mathcal{B}_n$ , where  $n$  is a positive integer. By [2, Proposition 19], the number of  $\mathcal{R}$  [ $\mathcal{L}$ ] of  $S_a$  is less than  $m = \frac{n}{2}$ . Thus, each  $\mathcal{D}$  of  $S$  has at most  $m$   $\mathcal{R}$  [ $\mathcal{L}$ ]-classes. By the way of Shützenberger representation,  $S$  is embedded in the direct product of row-monomial or column-monomial matrix semigroups  $S_i$  of less

than  $m$  over groups  $G_i$  with zero. Then each  $S$  has idempotent-separating congruence  $\rho$  such that  $S/\rho$  is embedded in the direct product of row-monomial or column-monomial matrix semigroups  $S_i$  of rank less than  $m$  over a single-element groups  $\{e\}$  with zero. Then for any  $s \in S$ ,  $s^{m!}$  is an idempotent. So,  $S/\rho$  is periodic. Thus, by Restivo and Reutenauer's result,  $S/\rho$  has only finitely many idempotents, and so does  $S$ .

**Remark.** In the proof above, row-monomial matrix semigroups of rank  $m$  over a single-element group are the partial transformation semigroups of a set of  $m$  elements.
