Abstract

To design optimal mechanical structures, design sensitivity analysis technique using higher order derivatives is important. However, usual techniques for computing the derivatives, for example numerical differential method, are very hard to be applied to real scale structures because of their large amount of the computational time, and the accumulation of the computational errors.

To overcome the problem, we study a new approach for the higher order sensitivity analysis of a finite element method by the differential algebraic method. The method automatically transforms Fortran functions into special purpose ones, which compute both the value of the given functions and their derivatives. The algorithm used in the method automatically and efficiently computes accurate values of higher order partial derivatives of a given function with many variables.

This paper reports the basic principles of the differential algebraic method and some experiments on the sensitivity analysis of mechanical structures. The original program of structural analysis by finite element method is implemented in Fortran. Using the proposed method, we get more accurate sensitivity and prediction values compared with usual numerical differentiation. We also discuss the effectiveness of the proposed a new approach for the higher sensitivity analysis of the mechanical structures.

1 Introduction

The importance of the sensitivity analysis using the finite element method (FEM) has been recognized to get higher precision and higher functionalities of mechanical structures in the structural design optimization(Haftka et al 1986a; Brebbia et al 1989; Eschenauer et al 1990). For example, to evaluate dynamical characteristics of structures, we use the modal analysis techniques(Ozaki 1988). The optimal mechanical design has been studied by the sensitivity analysis using the method. The traditional sensitivity analysis methods are such methods as a direct differential method, adjoint variable method, and numerical differential method(Adelman et al 1986; Haftka et al 1989). Those techniques for the sensitivity analysis(Haftka et al 1989; Kleiber
1993) require numerically computed partial derivatives of the objective functions (Vanderplaats 1984). Jacobian or Hessian matrices are used to compute optimal values by Newton- or quasi-Newton algorithms (Evtushenko 1985; Ratschek et al 1988). However, there are several problems for the computation: (1) truncation and rounding errors become large when numerically executing the sensitivity analyses, (2) much computation time is required to compute higher order derivatives to get optimal solutions, and (3) it is difficult to develop programs for computing higher order derivatives of a function with very many variables (e.g., Vanhonacker 1980; Belle 1982; Haug et al 1982; Jawed et al 1984; Haftka et al 1986b; Wanxie et al 1986; Dailey 1989).

To solve the problem, we have studied a new approach for higher order sensitivity analysis of FEM using an automatic differentiation method (Ozaki 1991; 1992; 1993b; Ozaki and Kimura 1994; Ozaki et al 1995). Our using tool: DAFOR for differential algebraic method method is a pre-processor for usual Fortran compilers (Berz 1989; 1990a). Users of the tool first input their Fortran function programs to compute the values of the functions with very many variables for the FEM structural analysis by the differential algebraic technique. Next, the tool analyzes the input program and inserts statements to compute higher order partial derivatives of the function. Then, the tool automatically generates a special Fortran program with sensitivity analysis capability. The method of the code generation to compute partial derivatives concerning many variables is attained by the automatic differentiation technique developed by Iri (1984), Roll (1986), Berz (1989; 1990b), Iri and Kubota (1991), and Griewank et al (1991). The unique feature of the differential algebraic method is that the technique can compute higher order partial derivatives with very high accuracy (Berz 1989; Ozaki 1991). The generated program is free from both truncate and rounding errors (Iri and Kubota 1991; Griewank et al 1991). Therefore, the using tools, the users can easily carry out sensitivity analysis for optimizing structural design problems.

This paper describes the principles of the differential algebraic method and reports the computational results of the FEM codes generated by the method applied to a plane truss structure. Dixon et al (1988) theoretically discuss the importance of the automatic differentiation techniques for finite element optimization, however, they do not show numerical results of the method. On the other hand, in this paper, we emphasize the theory as well as the experimental results. The results indicate that the technique and the use of sensitivity analysis by FEM generated by the differential algebraic technique are very effective in the sense that (1) unlike usual sensitivity analyses for FEM methods (e.g., Fox et al 1968; Wu and Arora 1986; Haftka et al 1989; Jao and Arora 1992; Kleiber 1993), the generated program can simultaneously compute the values of partial derivatives of a given function with very high accuracy, and that (2) the values of higher partial derivatives computed by the generated program and the one computed by usual re-analysis by the FEM coincide each other.

This paper organized as follows: In section 2, the basic principles of the differential algebraic method is introduced. In section 3, we have carried out some experiments to apply by the differential algebraic technique to sensitivity analysis. In section 4, we give some concluding remarks.
2 Basic Principles of Differential Algebraic Method

In this section, we will provide the mathematical background of the theory of differential algebraic method. Differential algebraic method are, in general, based on the direct application of the chain rule for computing partial derivatives of a composit function of a given function with many variables. In the following, we will describe the outline of the mathematical theory based on Berz (1989; 1990a). We will also provide the mathematical background of the theory of differential algebraic method required for the promised study of non-linearities. It is an application of the relatively new field of Nonstandard Analysis, which allows the introduction of arbitrarily small quantities, *infinitesimals*, in a rigorous theory of analysis.

2.1 Principle of First Order Partial Derivatives by Differential Algebraic Method

Consider the vector space $R^2$ of ordered pairs $(a_0, a_1), a_0, a_1 \in R$, in which an addition and a scalar multiplication are defined in the usual way:

\[
(a_0, a_1) + (b_0, b_1) = (a_0 + b_0, a_1 + b_1)
\]  
\[
t \cdot (a_0, a_1) = (t \cdot a_0, t \cdot a_1)
\]  

for $a_0, a_1, b_0, b_1 \in R$. Besides the above addition and scalar multiplication a multiplication between vectors is introduced in the following way:

\[
(a_0, a_1) \cdot (b_0, b_1) = (a_0 \cdot b_0, a_0 \cdot b_1 + a_1 \cdot b_0)
\]  

for $a_0, a_1, b_0, b_1 \in R$. With this definition of a vector multiplication the set of ordered pairs becomes an algebra, denoted by $D$.

Note that the multiplication is the same one would obtain by multiplying $(a_0 + a_1 \cdot x)$ and $(b_0 + b_1 \cdot x)$ and keeping terms linear in $x$.

Similarly, as in the case of complex numbers, one can identify $(a_0, 0)$ as the real numbers $a_0$. Although as a complex number, $(0, 1)$ is a root of $-1$, here it has another interesting property:

\[
(0, 1) \cdot (0, 1) = (0, 0),
\]  

which follows directly from equation (3). So $(0, 1)$ is a root of 0. Such a property suggests thinking of $d = (0, 1)$ as something infinitely small; so small in fact that its square vanishes. Consequently, we call $d = (0, 1)$ the differential unit. The first component of the pair $(a_0, a_1)$ is called the real part, and the second component is called the differential part.
It is easy to verify that \((1,0)\) is a neutral element of multiplication, because according to equation (3)

\[
(1,0) \cdot (a_0, a_1) = (a_0, a_1) \cdot (1,0) = (a_0, a_1)
\]  

(5)

It turns out that \((a_0, a_1)\) has a multiplicative inverse if and only if \(a_0\) is nonzero; so \(iD_1\) is not a fileld. In case \(a_0 \neq 0\), the inverse is

\[
(a_0, a_1)^{-1} = (\frac{1}{a_0}, -\frac{a_1}{a_0})
\]

(6)

It is easy to check that in fact \((a_0, a_1)^{-1} \cdot (a_0, a_1) = (1,0)\). The space \(iD_1\) is a subspace of the field \(R^*\) introduced in Nonstandard Analysis. Besides the usual real number, \(R^*\) contains a variety of infinitely small and infinitely large quantities. The outstanding result of the theory of Nonstandard Analysis is that differentiation becomes an algebraic problem: a function \(f\) is differentiable if and only if for any arbitrary small quantity \(\delta\), the real part of the quotient,

\[
\frac{f(x + \delta) - f(x)}{\delta},
\]

(7)

is independent of the choice of the specific \(\delta\). Thus, given any differentiable function \(f\), we can compute its derivatives just by evaluating the formula for a special choice of \(\delta\). We choose \(\delta = d = (0,1)\) and thus obtain

\[
\begin{align*}
    f'(x) &= \Re \left[ \frac{f(x + d) - f(x)}{d} \right] \quad \text{or} \\
    f'(x) &= \vartheta [f(x + d) - f(x)] = \vartheta [f(x) + d],
\end{align*}
\]

(8)

where \(\Re\) denote the real part, and \(\vartheta\) denotes the differential part. In the last step use has been made of the fact that \(f(x)\) has no differential part. Hence differential algebras are useful to compute derivatives directly, without requiring an analytic formula for the derivatives and without the inaccuracies of numerical techniques.
2.2 Principle of Higher Order Partial Derivatives by Differential Algebraic Method

We define $N(n,v)$ to be the number of monomials in $v$ variables through order $n$.

We will show that $N(n,v) = \frac{(n+v)!}{n!v!} = C(n+v, v)$, where $C(i,j)$ is the familiar binomial coefficient. First note that the number of monomials with exact order $n$ equals $N(n,v-1)$ because each monomial of exact order $n$ can be written as a monomial with one variable less times the last variable to such a power that the total power equals $n$. Thus we have $N(n,v) = N(n-1,v) + N(n,v-1)$: the number of monomials in $v$ variables through order $n$ equals the number of relation is satisfied by $C(n+v,v)$. Since also, obviously, $C(1+1,1) = 2 = N(1,1)$, the formula follows by induction.

Now assume that all these $N$ monomials are arranged in a certain manner order by order. For each monomial $M$, we call $I_M$ the position of $M$ according to the ordering. Conversely, with $M_I$ we denote the $I$th monomial of the ordering. Finally, for an $I$ with $M_I = x_1^{i_1} \cdots x_v^{i_v}$, we define $F_I = i_1! \cdots i_v!$.

We now define, in addition, a scalar multiplication and a vector multiplication on $\mathbb{R}^N$ in the following way:

\[
(a_1, \ldots, a_N) + (b_1, \ldots, b_N) = (a_1 + b_1, \ldots, a_N + b_N)
\]

\[
t \cdot (a_1, \ldots, a_N) = (t \cdot a_1, \ldots, t \cdot a_N)
\]

\[
(a_1, \ldots, a_N) \cdot (b_1, \ldots, b_N) = (c_1, \ldots, c_N)
\]

where the coefficients $c_i$ are defined as follows:

\[
c_i = F_I \sum_{0 \leq \nu \leq N} \frac{a_{i_{\nu}} \cdot b_{i_{\nu}}}{F_{i_{\nu}} \cdot F_{i_{\nu}}}
\]

To help clarify these definitions, let us look at the case of two variables and second order. In this case, we have $n = 2$ and $v = 2$. There $N = C(2+2,2) = 6$ monomials in two variables, namely,

\[1, x, y, xx, xy, yy.\]

As an example, using the ordering in equation (13), we have $I_{xy} = 5$ and $M_5 = y$. Using the ordering in equation (13), we obtain for $c_1$ through $c_6$ in equation (12):
\[
c_1 = a_1 \cdot b_1 \\
c_2 = a_1 \cdot b_2 + a_2 \cdot b_1 \\
c_3 = a_1 \cdot b_3 + a_3 \cdot b_1 \\
c_4 = 2 \cdot (a_1 \cdot b_4/2 + a_2 \cdot b_2 + a_4 \cdot b_1/2) \\
c_5 = a_1 \cdot b_5 + a_2 \cdot b_3 + a_3 \cdot b_2 + a_5 \cdot b_1 \\
c_6 = 2 \cdot (a_1 \cdot b_6/2 + a_3 \cdot b_3 + a_6 \cdot b_1/2).
\]

On \( \mathcal{D}_v \) we introduce a third operation \( \partial_i \):

\[
\partial_i(a_1, \ldots, a_N) = (c_1, \ldots, c_N)
\]

with

\[
c_i = \begin{cases} 
0 & \text{if } M_i \text{ has order } n \\
a_{i(M, x_i)} & \text{otherwise}
\end{cases}
\]

So \( \partial_v \) moves the derivatives around in the vector. Suppose a vector contains the derivatives of the function \( f \); then applying \( \partial_v \) to it in one obtains the derivatives of \( \frac{\partial f}{\partial x_v} \) through one order less.

Although in \( \mathcal{D}_1 \), \( d = (0,1) \) was an infinitely small quantity, here we have a whole variety of infinitely small quantities with the property that high-enough powers of them vanish. We give special names to the ones in components \( f \) belonging to first-order monomials, denoting them by \( dM_i \). In the example of \( \mathcal{D}_2 \), we have \( dx = (0,1,0,0,0,0) \), and \( dy = (0,0,1,0,0,0) \). It then follows from the theory of Nonstandard Analysis that instead of equation (8) we obtain

\[
f(x + dx, y + dy) = (f, \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial^2 f}{\partial x^2}, \frac{\partial^2 f}{\partial x \partial y}, \frac{\partial^2 f}{\partial y^2})(x,y).
\]

In the general case of \( v \) variables and order \( n \), after evaluating \( f \) in the differential algebra one obtains

\[
\frac{\partial^{i_1+i_2+\ldots+i_v} f}{\partial x_1^{i_1} \partial x_2^{i_2} \ldots \partial x_v^{i_v}} = c_{I(i_1 \ldots i_v)}
\]

where \( I(x_1^{i_1} \ldots x_v^{i_v}) \) is the index of the monomial \( (x_1^{i_1} \ldots x_v^{i_v}) \), as defined in the beginning of this section.
3 Sensitivity Analysis for Optimal Mechanical Design by the Differential Algebraic Technique

We have applied the differential algebraic method to sensitivity analysis problems with the FEM, which is the most popular in structural analyses. In the case studies described below, differential algebraic method is used to investigate the sensitivity of design variables of mechanical structures. The differential algebraic method can be applied to both linear and non-linear equations (Berz 1989; Ozaki 1991), if the equations are $n$-th order differentiable. Moreover, using the method, we can highly accurately compute higher order partial derivatives with many variables.

In the case studies, we have applied the method to two-dimensional linear FEM problems of structural analyses (Ozaki 1989).

3.1 Example: First- and Higher-Order Sensitivity Analysis

The code of sensitivity analysis of FEM using the differential algebraic method has been applied to a plane truss structure. The model is a simple static model shown in Figure 1, by which we simulate a train passing over an iron bridge. It consists of eight nodes and thirteen truss elements. The boundary conditions are that the node 7 and 8 are fixed, and that the nodes 1, 2, and 3 respectively have the loads 10,000 kgf, 20,000 kgf, and 10,000 kgf.

The experiment is the sensitivity analysis of the important stress for the fracture mechanics. The sensitivity analysis as to the stress of each element against the radius of each element is executed. The experiments are to compute the values of first and higher order partial derivatives and to predict the stress of each element against radius of each element. The object to compute the values of higher order partial derivatives is to indicate effectiveness of Taylor Series Expansion using coefficient of differential of higher order when the machine structures are large changing design in order to optimize. In particular, the method is very effective when the connection of nonlinearity is existed between object function and design variables. The relation of the stress of each element...
against radius of each element is non-linear.

The sensitivity as to the stress of each element against radius of the element 1 through 13 is computered. The highest sensitivity of element against radius of each element is the case of radius of element 2. The values of first and higher order partial derivatives as to the stress of element 2 against radius of the element 2 computered as is shown in Table 1.

( %): difference value between expected value and re-analysis by FEM  D.A.: Differential algebraic method

As to the sensitivity analysis the values of responses according to the value of changing design variables, the first and higher order partial derivatives was computered using a differential algebraic method in Table 2. The objective of this analysis is in order to examine the effectiveness of higher order differential coefficient against non-linearity. When we have changed the values of radius of the element 2 to 1%, 5%, 10%, 20%, 30%, 40%, and 50% increases, we have gotten the results shown in Table 2 by computing the compressive stress of element 2 by the higher order partial derivatives obtained using a differential algebraic method. The result of direct re-computation by FEM above the condition is shown in Table 2. The results of the compressive stress of element 2 predicted by the first order sensitivity analysis using a differential algebraic
method and the ones by the direct re-computation by FEM do not coincide with each other when the changes of design variables are large, on the other hand the results of the compressive stress of element 2 predicted by the higher order sensitivity analysis and the ones by the direct re-computation by FEM coincide with each other even if the changes are so large. Figure 2 illustrates the results of the computation shown in Table 2, and Figure 2 illustrates the values of differences between the results predicted by first and higher order sensitivity analysis and re-computational values of the compressive stress of element 2 by FEM.

4 Concluding Remarks

Using the differential algebraic technique, we observed the following advantages in the analyses.

(1) We can very easily and quickly execute sensitivity analysis of structural design problems.

(2) We can also predict the effects of changing design parameters with high accuracy.

The most remarkable feature of the differential algebraic method is that the method can simultaneously compute the values of higher order partial derivatives. This results in the following effects in the sensitivity analyses.

(3) Our method is superior to the conventional ones using numerical differentiation, because our method do not produce much with rounding error and truncating error in numerical computational process of sensitivity analysis.

(4) Our method is very effective when changing quantity of the design parameters become larger the non-linearity.

Acknowledgements

In this research, the authors would like to appreciate Prof.M.Berz(The Michigan State University) for supporting this study and suggesting important comments on the differential algebraic technique.
