Dynamical processes in macroscopic systems can be categorized typically into three hierarchical stages. First, the initial dynamical stage is concerned with the precise information of microscopic level, to which the Liouville or von Neumann equation is relevant. Secondly, the kinetic stage is described on the basis of the Boltzmann equation, where the microscopic basis of the second law of thermodynamics was elucidated as well as irreversibility. Thirdly, the thermo-hydordynamical stage comes, which is described in terms of hydrodynamics and thermodynamics. Variational principles relevant to these three stages are presented, which shows that the dynamical basis of irreversibility comes about as a result of the information contraction of the state of the system.

§1. Introduction

Corresponding to the hierarchy of development of dynamical systems, we have three sorts of variational principles, which are converted into one another by contracting informations of the state of the system, as shown in the table below. We begin with the kinetic theories of conduction electrons in solids based on the Boltzmann equation, for which a variational principle we call the Umeda-Kohler-Sondheimer (abbreviated as UKS) principle is presented as an extremum problem in §2, whose thermodynamical meaning is given on the basis of the entropy production. The extremum gives such a transport coefficients as electrical conductivity.
Contracting the information of the distribution function, we can derive the hydrothermodynamical variational principle which was obtained by Onsager\textsuperscript{2} many years ago by applying the theory of stochastic processes to the system at thermal equilibrium.

In §3 we investigate the dynamical stage on the basis of the von Neumann equation, for which a variational principle\textsuperscript{3} formulated as a stationarity problem. By means of the information contraction the stationarity problem is converted into an extremum problem. This contraction is presented in §4, where the variational principle is reduced to the UKS principle in a more rectified form\textsuperscript{4}. In §5 it is summarized how the contraction of information of the density matrix and distribution function convert the variational principle of reversible dynamical processes into the one of irreversible thermodynamical processes.

$\S 2$. UKS and thermodynamical variational principles

The Boltzmann equation in the kinetic theory is written

$$\frac{\partial f}{\partial t} = \left( \frac{\partial f}{\partial t} \right)_c + \left( \frac{\partial f}{\partial t} \right)_p,$$

(1)

as the sum of the collision and drift terms, which are given by

$$\left( \frac{\partial f}{\partial t} \right)_p = -eE \cdot \frac{\partial f}{\partial p} - \frac{p}{m} \cdot \frac{\partial f}{\partial r},$$

(2)
\[
\left( \frac{\partial f}{\partial t} \right)_c = \Sigma \cdot \, W_{k \cdot k} \cdot \delta(\epsilon_k - \epsilon_k') \cdot (f_k - f_k'),
\]  

(3)

respectively, for the system of conduction electrons in solids scattered by static impurities, where the transition probability is written

\[
W_{k \cdot k'} = \frac{2\pi |\langle k | V | k' \rangle|^2}{\hbar}
\]

(4)
in terms of the impurity potential \( V \).

Assuming

\[
f_k(r,t) = f_\theta - \frac{\partial f_\theta}{\partial \epsilon} \phi_k
\]

(5)
in terms of the Fermi distribution

\[
f_\theta(\epsilon) = \frac{1}{\exp[\beta(\epsilon - \mu)] + 1}
\]

(6)

we obtain

\[
\left( \frac{\partial f}{\partial t} \right)_c = \frac{\partial f_\theta}{\partial \epsilon} \cdot L_\Phi,
\]

(7)

from (3), where the collision operator \( L \) is defined by

\[
L_\Phi(k) = \Sigma \cdot \, W_{k \cdot k} \cdot \delta(\epsilon_k - \epsilon_k') \cdot (\phi_k - \phi_k').
\]

(8)
The drift term (1) is written as

\[
\left( \frac{\partial f}{\partial t} \right)_D = - \frac{\partial f_\theta}{\partial \epsilon} \left( j_k \cdot X_1 + q_k \cdot X_2 \right),
\]

(9)
in terms of the flows and forces

\[
j_k = ev_k, \quad q_k = (\epsilon_k - \mu)v_k, \quad (v_k = \hbar k/m)
\]

(10)
\[ x_1 = -e (\nabla \mu / e), \quad x_2 = -(\nabla T) / T. \]  (11)

Substituting (7) and (9) into (1), we get the linearized Boltzmann equation

\[ L\phi = X, \quad X = j_k \cdot X_1 + q_k \cdot X_2 \]  (12)

in the wave number k-space.

With respect to the inner product defined as

\[ (\phi, \psi) = (\phi, \psi) = -\sum_k \frac{3f_0(\epsilon)}{2\epsilon} \phi_k \psi_k, \]  (13)

\[ (\psi, L\phi) = \sum_k \frac{3f_0}{2\epsilon_k} W_{\psi \psi_k} \delta(\epsilon_k - \epsilon_k) (\psi_k - \psi_k \cdot)(\phi_k - \phi_k \cdot), \]  (14)

satisfies the self-adjoint and positive definite relations

\[ (\phi, L\phi) = (\phi, L\phi), \]  (15)

\[ (\phi, L\phi) \geq 0. \]  (16)

Thus observed values of the electric and heat currents are expressed as

\[ j_i = \sum_k f_k (j_1) \cdot \epsilon = (\phi, j_i) \quad (i = 1, 2), \]  (17)

where we rewrite \( j_1 = m_j, j_2 = m_q \). Putting the solution of (12) as

\[ \phi = x_1 \cdot \phi_1 + x_2 \cdot \phi_2, \]  (18)

we get

\[ L\phi_i = j_i. \]  (19)

Thus we can rewrite (16) as
\[
J_i = \sum_{j=1}^{2} L_{i,j} \cdot X_j \quad (i=1,2),
\]

(20)

confining ourselves to an isotropic or cubic system, where

\[
L_{i,j} = L_{i,j} = (\Phi_i, L\Phi) = (j_i, L^{-1} j_i) = \int_0^\infty (j_i, j_i(t)) dt \quad (i,j=1,2),
\]

(21)

\[
j_i(t) = e^{-\frac{t}{T}} j_i.
\]

(22)

which show Onsager's reciprocity relation.

Based on the relations (15) and (16), the Umeda-Kohler-Sondheimer (UKS) variational principle is presented as follows.

[I] \( (\psi, L\psi) = \text{Max. on the condition } (\psi, L\psi) = (\psi, X) \).

(23)

[II] \( 2(\psi, X) - (\psi, \psi L\psi) = \text{Max.} \).

(24)

[III] \(
\frac{(\psi, X)^2}{(\psi, L\psi)} = \text{Max.}
\)

(25)

The maximum gives the entropy production, which is equal, if \( X \) is an orthogonal component of the electric current, to the electrical conductivity. Changes of entropy with time due to collisions and drift are written as

\[
\left. \frac{dS}{dt} \right|_c = \frac{(\Phi, L\Phi)}{T},
\]

(26)

\[
\left. \frac{dS}{dt} \right|_o = -\frac{(\Phi, X)}{T}
\]

(27)

repectively. The entropy production (25) is intrinsic to the system. Using (18) and (19), we can rewrite (26) and (27) as

\[
\left. \frac{dS}{dt} \right|_c = \sum_{i=1}^{2} (L^{-1})_{i,i} J_i J_i
\]

(28)
\[
\left( \frac{\partial S}{\partial t} \right)_0 = \Sigma J_i X_i, \tag{29}
\]

in terms of the flows and forces. The UKS principle, when reproposed merely with respect to \( J_i \)'s, is much contracted, and we obtain the thermodynamical variation principle, which was obtained by Onsager based on a probabilistic augument and stated as

\[
2 \Phi J_i X_i = \Sigma \Phi (L^{-1}) \left( J_i J_i \right) = \text{Max}. \tag{30}
\]

with respect to \( J_i \)'s without reference to \( \phi \) as in UKS.

§3. Dynamical or quantum-statistical variational principle

The von-Neumann equation for the system exposed to an electric field \( \mathbf{E}(t) \) is expressed as

\[
i \hbar \frac{\partial \rho}{\partial t} = \left[ H - \mathbf{P} \cdot \mathbf{E}(t), \rho \right], \tag{31}
\]

in terms of the Hamiltonian \( H \) and the polarization operator \( \mathbf{P} \) of the system and a time dependent external electric field \( \mathbf{E}(t) \). We assume

\[
\rho(t) = \rho_c + \rho_i(t), \tag{32}
\]

\[
\rho_c = K \exp(-\beta H - \xi N) \tag{33}
\]

\[
\rho_i(t) = \int_0^\infty d\lambda \rho_c \exp(\lambda H) \Phi(t) \exp(-\lambda H), \tag{34}
\]

which correspond to (5) for the Boltzmann equation. Substituting (31) into (30) with (32) and (33), we get

\[
\frac{\partial \Phi}{\partial t} + L \Phi = \mathbf{j} \cdot \mathbf{E}(t), \tag{35}
\]

where we have defined \( L \) by
L\Phi = -i[H, \Phi]/\hbar, \quad \psi = i[H, \Phi]/\hbar. \quad (36)

Assuming for the applied electric field in analogy with incoming and outgoing waves in the scattering theory as

\[ E(t) = E \exp(st) \quad (t < 0), \quad \lim_{t \to -\infty} \rho(t) = \rho_c, \quad (37) \]

\[ E(t) = E \exp(-st) \quad (t > 0), \quad \lim_{t \to \infty} \rho(t) = \rho_c, \quad (38) \]

in terms of an adiabatic parameter \( s(>0) \), and also

\[ \Phi(t) = \Phi^{(+)} \exp(st) \quad (t < 0), \quad (39) \]

\[ \Phi(t) = \Phi^{(-)} \exp(-st) \quad (t > 0). \quad (40) \]

Substituting (39) and (40) with (37) and (38) into (45), we obtain

\[ L_+ \Phi^{(+)} = j \cdot E, \quad (41) \]

\[ L_- \Phi^{(-)} = j \cdot E, \quad (42) \]

defining a superoperator

\[ L_+ = L + s, \quad L\Phi = i[H, \Phi]/\hbar. \quad (43) \]

Let us define the inner product

\[ (\Phi, \Psi) = (\Psi, \Phi) = \int_0^\infty \text{Tr} \{ \Phi \rho_c \exp(\lambda H) \Psi \exp(-\lambda H) \} d\lambda. \quad (44) \]

Then the superoperator \( L_+ \) satisfies

\[ (\Phi, L_+ \Psi) = -(\Psi, L_- \Phi). \quad (45) \]

for any pair of operators \( \Phi \) and \( \Psi \). The quantum variational principle is presented as follows. Let us make
\[ W(\Phi^+, \Phi^-) = (\Phi^+ - \Phi^-, E \cdot j) + (\Phi^-, L_z \Phi^+) \]  \hspace{1cm} (46)

stationary with respect to \( \Phi^+ \) and \( \Phi^- \). Then the solutions satisfy (55) and (56), respectively, and gives the Joule heat

\[ W = J_z \cdot E = -J_{-z} \cdot E, \] \hspace{1cm} (47)

to (46), where \( J_z \) and \( J_{-z} \) are the current at \( t=0 \) for the states governed by (41) and (42), respectively. If \( \vec{E} \) is a unit vector parallel to the \( \mu \)-axes, the stationary value of

\[ \sigma(\Phi_+, \Phi_-) = (\Phi_+ - \Phi_-, j_m) + (\Phi_-, L_\mu \Phi_+), \] \hspace{1cm} (48)

gives the electrical conductivity

\[ \sigma = \int_0^\infty \int_\mathbb{R} \text{Tr}(\rho \cdot j \cdot (t-i\hbar \lambda) j \cdot \lambda \cdot \lambda). \] \hspace{1cm} (49)

§4. Reduction of variational principle from the quantum to UKS

Let us write \( \Phi^{(\cdot)} \) and its time reversal \( \Phi^{(-\cdot)} \) as

\[ \Phi^{(\cdot)} = \Phi^{(\cdot)} + \Phi^{(\cdot)}, \hspace{1cm} \Phi^{(-\cdot)} = \Phi^{(-\cdot)} + \Phi^{(-\cdot)}, \] \hspace{1cm} (50)

where \( \Phi^{(\cdot)} \) and \( \Phi^{(\cdot)} \) are odd and even components of \( \Phi \) with respect to inversion of time. Eliminating \( \Phi^{(\cdot)} \) in (46) into which (50) are substituted, we get

\[ W(\Phi') = 2(\Phi', j \cdot E) - (\Phi', \Lambda \Phi'), \] \hspace{1cm} (51)

where \( \Lambda \) is defined by

\[ (\Phi, \Lambda \Psi) = \sum_{\alpha \beta} \frac{\rho_n - \rho_n}{E_n - E_n} \frac{\hbar^2 s^2 + (E_n - E_n)^2}{\hbar^2 s} (m \Phi | n)(n | \Psi | m) \] \hspace{1cm} (52)

including a singular term inverse to \( s \) and satisfies

\[ (\Phi, \Lambda \Psi) = (\Psi, \Lambda \Phi), \] \hspace{1cm} (53)
\[(\Phi, \Lambda \Phi) \geq 0. \quad (54)\]

Thus we get the UKS type principle. Maximizing (65) as to \( \Phi' \), we get a master equation

\[\Lambda \Phi' = j \cdot \mathbf{E}. \quad (55)\]

The maximum is the Joule heat generated in the system and the electrical conductivity for a special case. So as to remove such a singular term as in (52), we decompose \( \Phi^{(+)} \), \( \Phi^{(-)} \) into diagonal and off-diagonal parts in the scheme of diagonalizing the unperturbed Hamiltonian \( H_0 \) as

\[\Phi^{(+)} = \Phi^{(+)}_d + \Phi^{(+)}_c, \quad \Phi^{(-)} = \Phi^{(-)}_d + \Phi^{(-)}_c, \quad (56)\]

and then introduce decompositions

\[\Phi^{(+)}_d = \Phi^{(+)}_e + \Phi^{(+)}_o, \quad \Phi^{(-)}_d = -\Phi^{(+)}_e + \Phi^{(+)}_o, \quad (57)\]

as to time reversal into odd and even components. Contracting (46) in these terms, we get

\[W(\Phi') = 2(\Phi', j \cdot \mathbf{E}) - (\Phi', L \Phi'), \quad (58)\]

where \( L \) is defined for any diagonal operator \( D \) by

\[LD = \frac{2\pi}{\hbar} \sum_{\xi} |a\rangle \langle a| \xi \langle a| T(E_a + i\xi) |b\rangle |b\rangle \delta(E_a - E_b) (D_a - D_b), \quad (59)\]

and satisfies

\[(\Phi', L \Phi') = (\Phi', L \Phi'), \quad (60)\]

\[(\Phi', L \Phi') \geq 0. \quad (61)\]

Thus we get the variational principle maximizing (58), which is
similar to but more complex than the UKS case.

If we redefine the inner product as

\[(\Phi, \Psi) = (\Phi, \Phi) = \int_\beta^\infty \text{Tr}(\Phi \rho_\beta \exp(\lambda H_\beta) \Psi \exp(-\lambda H_\beta)) d\lambda, \tag{62}\]

in terms of the thermal weight

\[\rho_\beta = K_\beta \exp[-\beta(H_\beta - \mu N)] \tag{63}\]

for the unperturbed Hamiltonian $H_0$, we can rewrite (58)

\[W(\Phi_\beta') = 2(\Phi_\beta', j \cdot E) - (\Phi_\beta', \mathbf{L}\Phi_\beta'), \tag{64}\]

which is the most fundamental, rectified form of the UKS principle. Maximizing (64) with $\Phi_\beta'$ gives a sort of master equation

\[\mathbf{L}\Phi_\beta' = j \cdot E, \tag{65}\]

which reduces to the Boltzmann equation for conduction electrons with the collision term written in terms of the $T$-matrix.

§5.Conclusion

The quantum variational principle concerning the von Neumann equation in the system of conduction electrons exposed to an applied electric field presented as a stationarity problem was transformed into the UKS maximum principle by means of information contractions. The maximization demands that diagonal elements of the odd component of density matrix or the distribution function of electron with respect to time reversal should satisfy the rectified Boltzmann equation with the collision term given in terms of the $T$-matrix. Further the UKS principle is reduced to the thermodynamical variation principle first due to Onsager.\(^2\)

That is to say, through successive contractions the quantum,
kinetic and thermodynamic variational principles, which governs
the three typical hierarchial stages of the thermodynamical system
are converted from one to another, exhibiting that irreversibility
comes about through contractions.
