Abstract

Verification of timed bisimulation equivalence is generally difficult because of state explosion caused by concrete time values. In this paper, we propose a verification method to verify timed bisimulation equivalence of two timed processes using a symbolic technique similar to [1]. We first propose a new model of timed processes, Alternating Timed Symbolic Labelled Transition System (A-TSLTS). In A-TSLTS, each state has some parameter variables and those values determine its behaviour. Each transition in an A-TSLTS has a guard predicate. The transition is executable if and only if its guard predicate is true under specified parameter values. In the proposed method, we can obtain the weakest condition for a state-pair in a finite A-TSLTS to make the state-pair be timed bisimulation equivalent. We also extend the method to verify untimed bisimulation equivalence [2, 3, 4].

Keywords: timed process, symbolic bisimulations, A-TSLTS, most general boolean, untimed bisimulation equivalence

1 Introduction

Verification of timed bisimulation equivalence for timed processes is generally difficult because of state explosion. There are some proposals to solve this problem[5, 6, 7, 4]. But they all have some restrictions in describing time constraints of actions. On the other hand, for data-passing processes, a verification method of bisimulation equivalence is proposed[1]. This method has some advantages: (1). Its verification cost does not depend on data domain nor absolute values of constants which we use in data constraints, and (2). the method does not depend on predicates which we choose for describing data constraints (although they should be decidable in order to verify the equivalence). It is desirable that there exists a method to verify timed bisimulation equivalence which has the same advantages as above.
In this paper, first, we propose a new model for describing timed processes, and then we propose a method to verify timed bisimulation equivalence of two timed processes in the proposed model using the technique so-called 'symbolic bisimulation' [1].

A new model, Alternating Timed Symbolic Labelled Transition System (A-TSLTS, for short), is introduced to describe time-constrained processes. Each state in an A-TSLTS may have some parameter variables (eg. $x$, $y$). Each transition in an A-TSLTS has a guard predicate such as 'execute the transition $a$ between $x+5$ and $y$ seconds from now.' The guard predicate of a transition may contain any parameter variables associated to its source state, any numerical operations on time domain, and any atomic predicates. We can use any logic. The logic only needs to be decidable in order to verify the equivalence in the proposed method. In this paper, only timed transitions are considered (data-passing is ignored).

We model a time transition by a delay transition $\frac{e(d)}{}$ with a delay variable $d$, which stands for an amount of the delay (duration). This is the same as [5]. This modeling has an advantage that we can treat durations equally as input/output data. So, although we only handle time here, we can easily extend the result to the model which handles both time and data-passing. Each delay transition $\frac{e(d)}{}$ and action transition $\frac{\alpha}{\cdot}$ have guard predicates which may contain the delay variables and the parameter variables at their source states (they possibly include some delay variables in former delay transitions). We refer to such a model as "Timed Symbolic Labelled Transition System (TSLTS)."

It is difficult to consider symbolic bisimulation [1] on a TSLTS. The reason is as follows. A delay transition $\frac{e(d)}{}$ whose amount of delay is $d$, is equivalent to a sequence of delay transitions $\frac{e(d_1)}{\cdot} \frac{e(d_2)}{\cdot} \cdots \frac{e(d_n)}{\cdot}$ where $d_1 + d_2 + \cdots + d_n = d$. Also, in a TSLTS, it is possible that after $\frac{e(d_1)}{\cdot}$ is executed, both $\frac{e(d_2)}{\cdot}$ and $\frac{\alpha}{\cdot}$ may be executable. So, in general, the sequence $\frac{e(d_1)}{\cdot} \frac{e(d_2)}{\cdot}$ is not easily reduced to one transition. In order to make a matching between two transitions which form a bisimulation, we must make a (possibly infinitely many) sequence-to-sequence matching, which makes the problem difficult. Therefore, in this paper, we assume our model to have alternating property. Each state of a TSLTS must belong to one of the two kinds of sets of states, the one is a set of idle states, and the other is a set of active states. From an idle state, only a delay transition is possible and then it moves to an active state. From an active state, some action transitions are possible. After one of them is executed, it comes back to an idle state. We call such a restricted TSLTS as an Alternating TSLTS (A-TSLTS). In the A-TSLTS model, we can make the bisimulation matching of delay transitions to one-to-one. Consecutive execution of actions (without delay) can be expressed in an A-TSLTS by inserting a delay transition of zero duration between two action transitions.

Using a similar algorithm as [1], from a given state-pair we obtain the weakest condition (similar to [1], we refer to the condition as most general boolean, mgb for short) to make the two states be timed bisimulation equivalent. For example, let us consider the following two processes, $P$ and $Q$. The process $P$ may execute the action $a$ between $x+5$ and $y$ seconds from now, or execute the action $b$ between $y$ and $x+10$ seconds from now. The process $Q$ may execute the action $a$ between $10$ and $z$ seconds from now. In order to make $P$ and $Q$ bisimilar, the condition "$(x+5 = 10) \land (y = z) \land (y > x+10)$" must hold (if $(y > x+10)$, then $P$ cannot execute the action $b$). On the other hand, the condition is also a sufficient condition to make $P$ and $Q$ bisimilar. Such a condition is the mgb. In the proposed method,
even if $P$ and $Q$ are infinite processes, if the corresponding A-TSLTS has finite states and finite variables, we can obtain the mgb for any two states. Once we obtain the mgb, we can verify whether the two states are timed bisimulation equivalent w.r.t. specified parameter values by checking whether the values satisfy the mgb.

The proposed algorithm takes an A-TSLTS and its state-pair as an input, and it outputs the mgb for the state-pair. We also show that the algorithm can easily be extended to verify untimed bisimulation equivalence[2], which is a bisimulation equivalence where we allow the executed time of actions does not have to be precisely equal. The notion of untimed bisimulation equivalence is essentially identical to time abstracted bisimulation in [3, 4].

This paper is organized as follows. In Section 2, the model of timed processes, A-TSLTS, is defined. In Section 3, timed bisimulation equivalence of states in an A-TSLTS is defined. In Section 4, an algorithm is presented to construct the mgb for two states in an A-TSLTS w.r.t. timed bisimulation equivalence. In Section 5, untimed bisimulation equivalence of states in an A-TSLTS is defined and an extension of the algorithm to verify untimed bisimulation equivalence is presented. Finally, in Section 6, we conclude this paper.

2 TSLTS model

A TSLTS is an LTS where each state $s$ has a set of parameter variables $DVar(s)$, and each transition is either an action transition, represented as $s \xrightarrow{a, P} s'$ or a delay transition represented as $s \xrightarrow{\epsilon(d), P} s'$. $a$ is an action name. $d$ is a variable which stands for a duration. Each $P$ is a transition condition. The transition condition $P$ is a formula of a (decidable) 1st-order arithmetics on any (dense or discrete) time domain. $P$ may contain any variables in $DVar(s)$ ($s$ is a source state of the transition). In a delay transition $s \xrightarrow{\epsilon(d), P} s'$, $P$ may also contain the variable $d$.

Intuitively, a delay transition $s \xrightarrow{\epsilon(d), P} s'$ represents a state-transition only by delay. Its duration is $d$ and $d$ must satisfy $P$ under a current assignment for other parameter variables in $DVar(s)$. The delay is possible up to the maximum value of $d$'s which satisfy $P$. The delay over the maximum value of $d$ is not allowed (time-deadlock[8], urgency[9]). When the transition is completed, the actual duration (which satisfies $P$) is assigned to the variable $d$. $DVar(s')$ may contain the variable $d$. So the value of $d$ may be used in conditions of any succeeding transitions. An action transition $s \xrightarrow{a, P} s'$ represents an execution of an action $a$ when $P$ holds under a current assignment for parameter variables in $DVar(s)$. The execution of an action is considered instantaneous, since we take interleaving semantics to express concurrency[10, 7]. The state $s$ may have multiple outgoing action transitions. In that case, one of executable action transitions is nondeterministically chosen and then executed.

Example 1 We show an example of a TSLTS in Fig. 1. In Fig. 1, for convenience, the names $s_1, s_2, \ldots$ are assigned for states and $t_1, t_2, \ldots$ for transitions. The set associated to each state $s_i$ represents $DVar(s_i)$. $a[P]$ (or $\epsilon(d)[P]$) associated to each transition represents an action name $a$ (or a delay with its duration of $d$, respectively) with a transition condition $P$. When a value $v$ is assigned to the parameter variable $x$ at state $s_i$, the TSLTS in Fig. 1
behaves as follows. First, \( x = v \) units of time is elapsed (the value \( v \) is assigned to \( d_{t_1} \)) and then the action \( a \) is executed. Next, before 4 units of time elapse, the action \( b \) or \( c \) is executed. The action \( b \) is executable when the duration is within 3 units of time. The action \( c \) is also executable when the duration is more than or equal to 2 units of time. In the case that \( c \) is executed, the TSLTS moves its state to \( s_1 \) and then repeats the behaviour from the beginning.

In order to make it easier to consider symbolic bisimulation, we restrict a TSLTS so that its states fall into two categories of states, idle states and active states. Each idle state has only a delay transition as an outgoing transition and the destination is an active state. An active state has only action transitions as outgoing transitions and all the destinations are idle states. We call this restricted TSLTS as an Alternating TSLTS (A-TSLTS). The notion of A-TSLTS is inspired by [11].

In the rest of this paper, we assume that each TSLTS is an A-TSLTS, and it is time-deterministic, i.e., every state has at most one outgoing delay transition. Time-determinacy is a reasonable assumption when we consider processes of real-world. Many other studies also assume time-determinacy[8, 10, 7].

**Example 2** The TSLTS of Example 1 is an A-TSLTS because a division into \( \{s_1, s_3, s_5\} \) (idle states) and \( \{s_2, s_4\} \) (active states) is possible. It is also time-deterministic.

## 3 Timed Bisimulation Equivalence

In this section, we define timed bisimulation equivalence for A-TSLTS. Before all, we need some preliminary definitions.

**Definition 1**

- We denote *assignments* of values to variables by \( \rho, \rho', \ldots \).

  - For a predicate \( P \) and an assignment \( \rho \), we denote \( \rho \models P \) iff \( P \) is true under an assignment \( \rho \).

  - We denote \( \rho[x = e] \) is the same assignment as \( \rho \) except that the value of the expression \( e \) is assigned to the variable \( x \).
We denote a tuple \((s, \rho)\) of a state \(s\) in a TSLTS and an assignment \(\rho\), as \(\rho(s)\). \(\rho(s)\) stands for a state with some parameter values (not variables) associated to \(s\). We call it an instance of \(s\) w.r.t. \(\rho\).

The actual moves of a TSLTS are formally defined by considering the corresponding (traditional) LTS, whose states are all instances of TSLTS states, and whose transitions are labelled by either an action name or a concrete value of a duration.

**Definition 2** For a TSLTS \(M\), its corresponding semantic LTS \(M'\) is defined as follows:

- The set of states in \(M'\) are the set of all instances of \(M\), i.e. \(\{\rho(s)|\rho:\text{an assignment, } s: \text{a state of } M\}\).
- Each transition in \(M'\) is labelled by either an action name \(a\) of \(M\), or any non-negative time value \(t\).
- For each transition \(s \xrightarrow{a,P} s'\) in \(M\) and each assignment \(\rho\), \(M'\) has a transition \(\rho(s) \xrightarrow{a} \rho(s')\) iff \(\rho \models P\).
- For each transition \(s \xrightarrow{(d),P} s'\) in \(M\), each assignment \(\rho\), and any non-negative time value \(t\), \(M'\) has a transition \(\rho(s) \xrightarrow{d = t} \rho[d=t](s')\) iff \(\rho[d=t] \models \exists d'[d \leq d' \land P\{d'/d\}] (P\{d'/d\}\) denotes \(P\) whose any occurrence of a free variable \(d\) is replaced by \(d'\). Moreover, for any non-negative time value \(t'\) which satisfies \(t' \leq t\), \(M'\) has a transition \(\rho[d = t'](s') \xrightarrow{t-t'} \rho[d = t](s')\).

**Remark:** The predicate \(\exists d'[d \leq d' \land P\{d'/d\}]\) means that \(P\) holds at some duration \(d'\) where \(d \leq d'\). In such a case, a delay of the duration \(d\) (as well as \(d'\)) is allowed.

For a given TSLTS, timed bisimulation equivalence of its two instances of states is defined by considering a traditional bisimulation equivalence on its semantic LTS.

**Definition 3** A timed bisimulation relation \(R\) is a binary relation on a set of instances of TSLTS states \(\{\rho(s)|s:\text{a TSLTS state, } \rho:\text{an assignment}\}\), which satisfies the following conditions:

- \(R\) is a symmetric relation, and
- if \((\rho_i(s_i), \rho_j(s_j)) \in R\), then all of the following conditions hold:
  - For any time value \(t\), if \(\rho_i(s_i) \xrightarrow{t} \rho'_i(s'_i)\), then there exist some \(s'_j\) and \(\rho'_j\) such that \(\rho_j(s_j) \xrightarrow{\rho'_j(s'_j)} (\rho'_i(s'_i), \rho'_j(s'_j)) \in R\),
  - For any action name \(a\) in the TSLTS, if \(\rho_i(s_i) \xrightarrow{a} \rho'_i(s'_i)\), then there exist some \(s'_j\) and \(\rho'_j\) such that \(\rho_j(s_j) \xrightarrow{a} \rho'_j(s'_j)\) and \((\rho'_i(s'_i), \rho'_j(s'_j)) \in R\).

If there exists some timed bisimulation equivalence \(R\) such that \((\rho_i(s_i), \rho_j(s_j)) \in R\), the two instances \(\rho_i(s_i)\) and \(\rho_j(s_j)\) are called timed bisimulation equivalent, which is denoted by \(\rho_i(s_i) \sim_t \rho_j(s_j)\). Especially, if \(\rho(s_i) \sim_t \rho(s_j)\), then the two states \(s_i\) and \(s_j\) are called timed bisimulation equivalent w.r.t. an assignment \(\rho\).
\[ mgb(s_i, s_j) \overset{\text{def}}{=} mgb1(s_i, s_j, \emptyset) \]
\[ mgb1(s_i, s_j, W) \overset{\text{def}}{=} \]

if \( (s_i, s_j) \in W \) then return true

else if \( (s_i, s_j) \) is a pair of idle states, then return \( \text{match}\_\text{delay}(s_i, s_j, W) \)

else if \( (s_i, s_j) \) is a pair of active states, then return \( \text{match}\_\text{action}(s_i, s_j, W) \)

else return false

\[ \text{match}\_\text{delay}(s_i, s_j, W) \overset{\text{def}}{=} \]

if \( s_i \xrightarrow{e(d_i), P_i} s_i' \) and \( s_j \xrightarrow{e(d_j), P_j} s_j' \)

then let \( d = \text{new}(DV\text{ar}(s_i) \cup DV\text{ar}(s_j)) \),

\[ M_{i', j'} = mgb1(s'_i|d_i \rightarrow d|, s'_j|d_j \rightarrow d|, W \cup \{(s_i, s_j)\}) \] in

return \( \forall d[P_1\{d/d_i\} \wedge M_{i', j'}] \wedge \forall d[P_2\{d/d_j\} \Rightarrow [P_i\{d/d_i\} \wedge M_{i', j'}]] \)

\[ e(d_i) \overset{P_i}{\rightarrow} e(d_j) \overset{P_j}{\rightarrow} \) then return true else return false

\[ \text{match}\_\text{action}(s_i, s_j, W) \overset{\text{def}}{=} \]

return \( \wedge_{a \in \text{Act}} \{\text{match}\_\text{action1}(a, s_i, s_j, W)\} \)

\[ \text{match}\_\text{action1}(a, s_i, s_j, W) \overset{\text{def}}{=} \]

let \( K = \{k|s_i \xrightarrow{a} s'_{i_k}\}, \) \( L = \{l|s_j \xrightarrow{a} q_l\} \),

\[ M_{k, l} = mgb1(s_{i_k}, s_{j_l}, W \cup \{(s_i, s_j)\}) \] in

return \( \wedge_{k \in K} \{P_k \Rightarrow \vee_{l \in L} \{Q_l \wedge M_{k, l}\}\} \wedge \vee_{l \in L} \{Q_l \Rightarrow \wedge_{k \in K} \{P_k \wedge M_{k, l}\}\} \)

where, for a set \( V \) of variables, \( \text{new}(V) \) denotes a function which returns an appropriate new variable \( x \) such that \( x \not\in V \).

Figure 2: Algorithm to compute \( mgb(s_i, s_j) \).

4 Verification of Timed Bisimulation Equivalence

For any state-pair \( (s_i, s_j) \) in an A-TSLTS, we call the weakest condition \( P \) such that if \( \rho \models P \) then \( s_i \) and \( s_j \) are timed bisimulation equivalent w.r.t. \( \rho \), as the \( mgb \) of \( (s_i, s_j) \). If we can obtain the \( mgb \) \( P \) for any state-pair \( (s_i, s_j) \), then the verification of timed bisimulation equivalence of \( \rho(s_i) \) and \( \rho(s_j) \) is reduced to the verification to check whether \( \rho \models P \).

To keep track of the correspondences between variables during matching, it is useful to replace some different variables of two states with some common name, standing for their matched common value which equates the two states. In order to do so, we consider the \( mgb \) for a pair of terms instead of states in A-TSLTS. This is similar to [1]. A term is a tuple of a state and a substitution. A substitution is a mapping from variables to variables. We denote a term \((s, \sigma)\) as \( s\sigma \), where \( s \) is a state of A-TSLTS and \( \sigma \) is a substitution. We also denote a substitution which maps the variable \( d \) to \( d' \) as \( [d \rightarrow d'] \). If \( \sigma \) is an identity substitution, we abbreviate \( s\sigma \) to \( s \) and we do not distinguish between the term \( s\sigma \) and the state \( s \). Note that if the set of variables is a finite set, then the set of all possible substitutions are finite. A transition between terms is defined as \( s\sigma \xrightarrow{e(\sigma(d), P)} s'\sigma \) (\( s\sigma \xrightarrow{a\sigma(P)} s'\sigma \) if \( s \xrightarrow{e(d), P} s' \) (\( s \xrightarrow{a(P)} s' \), respectively) in an A-TSLTS. We denote the \( mgb \) of a term-pair \((s_i, s_j)\) as \( mgb(s_i, s_j) \). If the A-TSLTS has only finite states and finite variables, \( mgb(s_i, s_j) \) is obtained by the algorithm in Fig. 2.

The function \( mgb(s_i, s_j) \) takes two arguments \( s_i \) and \( s_j \), any two states in an A-TSLTS, and returns the \( mgb \) for \((s_i, s_j)\). The function \( mgb1(s_i, s_j, W) \) takes three arguments \( s_i, s_j \) and a set \( W \) of state-pairs. \( W \) is a set of \textit{already visited} pairs, introduced to make sure the algorithm eventually terminates. For \((s_i, s_j) \in W \), it simply returns \( \text{true} \). Otherwise,
it returns $\text{match\_delay}(s_i, s_j, W)$ if $(s_i, s_j)$ is a pair of idle states, or $\text{match\_action}(s_i, s_j, W)$ if $(s_i, s_j)$ is a pair of active states. $\text{match\_delay}(s_i, s_j, W)$ ($\text{match\_action}(s_i, s_j, W)$) is a function which recursively computes the mgb for $(s_i, s_j)$, where we assume $(s_i, s_j)$ is a pair of idle (active, respectively) states.

The function $\text{match\_delay}(s_i, s_j, W)$ computes the mgb for two idle states $s_i$ and $s_j$ as follows. Firstly, from the definition of A-TSLTS and time-determinacy, delay transitions from $s_i$ and $s_j$ correspond to one-to-one, including duration values. So we unifies the delay variables in the two transitions into one. We introduce a new variable $d$ representing the common duration of delay. We choose $d = \text{new}(DVar(s_i) \cup DVar(s_j))$. w.r.t. a given assignment $\rho$, if $s_i$ and $s_j$ are timed bisimulation equivalent, and if any delay transition of duration $v$ from $s_i$ is possible, then there must exist a delay transition of the same duration $v$ from $s_j$, and the destinations $s'_i$ and $s'_j$ must be timed bisimulation equivalent w.r.t. $\rho[d = v]$. For example, if $s_i \xrightarrow{e(d_i), d_i \leq x} s'_i$ and $s_j \xrightarrow{e(d_j), d_j \leq y} s_j$, then $\forall d [d \leq x \implies d \leq y \wedge (\text{the mgb for } (s'_i[d_i \rightarrow d], s'_j[d_j \rightarrow d]))]$ holds. Here, in general, the mgb for $(s'_i, s'_j)$ contains the variables $d_i$ or $d_j$. To preserve the information that $d_i$ and $d_j$ are equal, we consider the mgb for $(s'_i[d_i \rightarrow d], s'_j[d_j \rightarrow d])$ instead. In general, the mgb for $(s'_i[d_i \rightarrow d], s'_j[d_j \rightarrow d])$ contains the variable $d$ as a free variable. It represents the mgb for $(s'_i, s'_j)$ in the case $d_i = d_j = d$ is assumed.

The above discussions must also be applied when $s_i$ and $s_j$ are exchanged. Thus, $\rho$ must satisfy the following condition if $s_i$ and $s_j$ are timed bisimulation equivalent w.r.t. $\rho$.

$$\forall d[P_i \{d/d_i\} \Rightarrow [P_j \{d/d_j\} \wedge M_{d', j'}]] \land \forall d[P_i \{d/d_i\} \Rightarrow [P_j \{d/d_i\} \wedge M_{d', j'}]]. \quad (1)$$

where $M_{d', j'} = \text{mgb}(s'_i[d_i \rightarrow d], s'_j[d_j \rightarrow d])$. On the other hand, if $s_i$ and $s_j$ are not timed bisimulation equivalent w.r.t. $\rho$, then, for example, a delay transition of some duration $v'$ is possible from $s_i$, which is impossible on $s_j$, or otherwise $s'_i$ and $s'_j$ are not equivalent w.r.t. $\rho[d = v'']$ for some value $v''$. In any case, Expression (1) does not hold. Therefore, Expression (1) is the weakest condition such that $\rho$ must satisfy in order to make $\rho(s_i)$ and $\rho(s_j)$ be timed bisimulation equivalent, i.e., the mgb for $(s_i, s_j)$. The function $\text{match\_delay}(s_i, s_j, W)$ computes $M_{d', j'} = \text{mgb1}(s'_i[d_i \rightarrow d], s'_j[d_j \rightarrow d], \{(s_i, s_j)\})$ recursively (where $(s_i, s_j)$ is treated as a already visited pair) and then returns Expression (1) as the mgb for $(s_i, s_j)$.

The function $\text{match\_action}(s_i, s_j, W)$ returns the mgb for active states $s_i$ and $s_j$, which is computed as follows. Firstly, if $s_i$ and $s_j$ are timed bisimulation equivalent w.r.t. an assignment $\rho$, for any action $a$ in a set $\text{Act}$ of all actions, the following condition holds. For any possible transition $s_i \xrightarrow{a P_k} s_{i_k}$ whose transition condition $P_k$ satisfies $\rho \models P_k$, if the action $a$ is executable, there must exist some transition $s_j \xrightarrow{a Q_l} s_{j_l}$ whose transition condition $Q_l$ also satisfies $\rho \models Q_l$, and the destinations $s_{i_k}$ and $s_{j_l}$ must be timed bisimulation equivalent w.r.t. $\rho$ ($\rho$ must satisfy the mgb for $(s_{i_k}, s_{j_l})$). The above discussions must be true when $s_i$ and $s_j$ are exchanged. Therefore, when we let $K = \{k|s_i \xrightarrow{a P_k} s_{i_k}\}$, $L = \{l|s_j \xrightarrow{a Q_l} s_{j_l}\}$ and $M_{k, l} = \text{mgb}(s_{i_k}, s_{j_l})$, $\rho$ must satisfy

$$\bigwedge_{k \in K} \{P_k \Rightarrow \bigvee_{l \in L} \{Q_l \land M_{k, l}\}\} \land \bigwedge_{l \in L} \{Q_l \Rightarrow \bigvee_{k \in K} \{P_k \land M_{k, l}\}\}. \quad (2)$$

A conjunction of Expression (2) over all actions $a \in \text{Act}$ is a condition such that $\rho$ must satisfy if $s_i$ and $s_j$ are timed bisimulation equivalent for any action w.r.t. $\rho$. On the other hand, if $\rho$
Figure 3: Example of A-TSLTS

does not make $s_i$ and $s_j$ be timed bisimulation equivalent, there must exist some action $a'$ such that, for example, $s_i \xrightarrow{a', P_k} s_{ik}$ is executable and for any $l$, either $s_j \xrightarrow{a', Q_l} s_{jl}$ is not executable or $s_{ik}$ and $s_{jl}$ are not timed bisimulation equivalent w.r.t. $\rho$. In any case, Expression (2) does not hold. Therefore, a conjunction of Expression (2) over all actions $a \in Act$ is the weakest condition that $\rho$ must satisfy to make $s_i$ and $s_j$ be timed bisimulation equivalent w.r.t. $\rho$, i.e. the mgb for $(s_i, s_j)$. The function $\text{match}_\text{action}(a, s_i, s_j, W)$ composes a conjunction of $\text{match}_\text{action}(a, s_i, s_j, W)$ over all $a \in Act$ and returns it as the mgb for $(s_i, s_j)$.

The algorithm $mgb(s_i, s_j)$ terminates if the considered A-TSLTS has only a finite number of states and variables (thus it has only a finite number of pair of terms).

Formally, we obtain the correctness result by the following theorem.

**Theorem 1** [Soundness] If $\rho \models mgb(s_i, s_j)$, then $\rho(s_i) \sim_t \rho(s_j)$. □

**Theorem 2** [Completeness] If $\rho(s_i) \sim_t \rho(s_j)$, then $\rho \models mgb(s_i, s_j)$. □

The formal proof of the correctness for this algorithm is similar to Appendix B. in [1]. We omit the detail due to the space restriction.

**Example 3** For a pair $(s_1, s_3)$ of the A-TSLTS in Fig. 3, $mgb(s_1, s_3)$ is obtained as follows.

$$mgb(s_1, s_3) = \forall d_1[d_1 = x \Rightarrow [d_1 = y \land M_{24}]] \land \forall d_1[d_1 = y \Rightarrow [d_1 = x \land M_{24}]]$$

where,

$$M_{24} = mgb(s_2[d_1 \rightarrow d_1], s_4[d_3 \rightarrow d_1], \{(s_1, s_3)\})$$

$$= [d_1 \leq 3 \Rightarrow [d_1 \leq 2 \land M_{13} \lor (d_1 < 1 \lor 2 < d_1 \leq 3) \land M_{15}]] \land$$

$$[d_1 \leq 2 \Rightarrow [d_1 \leq 3 \land M_{13}]] \land [(d_1 < 1 \lor 2 < d_1 \leq 3) \Rightarrow [d_1 \leq 3 \land M_{15}]],$$

$$M_{13} = mgb1(s_1, s_3, \{(s_1, s_3), (s_2, s_4)\}),$$

$$M_{15} = mgb1(s_1, s_5, \{(s_1, s_3), (s_2, s_4)\}) = \text{false}.$$  

Since $mgb1(s_1, s_3, \{(s_1, s_3), (s_2, s_4)\}) = \text{true}$, the mgb after simplification is

$$mgb(s_1, s_3) \equiv [x = y] \land [1 \leq x \leq 2 \lor x > 3].$$ □
5 Untimed Bisimulation Equivalence and its Verification

Definition 4 An untimed bisimulation relation \( R \) is a binary relation on a set of instances of TSLTS states \( \{\rho(s)|s:a \text{ TSLTS state}, \rho:an assignment\} \), which satisfies the following conditions:

- \( R \) is a symmetric relation, and
- if \((\rho_i(s_i), \rho_j(s_j)) \in R\), then all of the following conditions hold:
  - For any time value \( t \), if \( \rho_i(s_i) \xrightarrow{t} \rho'_i(s'_i) \), then there exist some \( s'_j, \rho'_j \) and some time value \( t' \) such that \( \rho_j(s_j) \xrightarrow{t'} \rho'_j(s'_j) \) and \((\rho'_i(s'_i), \rho'_j(s'_j)) \in R\),
  - For any action name \( a \) in the TSLTS, if \( \rho_i(s_i) \Rightarrow^a \rho'_i(s'_i) \), then there exist some \( s'_j \) and \( \rho'_j \) such that \( \rho_j(s_j) \Rightarrow^a \rho'_j(s'_j) \) and \((\rho'_i(s'_i), \rho'_j(s'_j)) \in R\). Here \( \Rightarrow^a \equiv \xrightarrow{t_1} \xrightarrow{a} \xrightarrow{t_2} \) for some time values \( t_1 \) and \( t_2 \).

If there exists some untimed bisimulation equivalence \( R \) such that \((\rho_i(s_i), \rho_j(s_j)) \in R\), the two instances \( \rho_i(s_i) \) and \( \rho_j(s_j) \) are called untimed bisimulation equivalent, which is denoted by \( \rho_i(s_i) \sim_u \rho_j(s_j) \). \( \square \)

The result of the previous section can be extended to untimed bisimulation equivalence. To do this, we modify a part of the algorithm in Section 4 as Fig. 6 to make durations not necessarily be equal when we match delay transitions.

The mgb of idle states is easily expressed by the following formula:

\[
\forall d[P_i\{d/d_i\} \Rightarrow \exists d'[P_j\{d'/d_j\} \land M_{i',j'}]] \land \forall d'[P_j\{d'/d_j\} \Rightarrow \exists d[P_i\{d/d_i\} \land M_{i',j'}]]
\]

where \( M_{i',j'} \) is the mgb of the next pair of active states.

On the other hand, in order to consider the mgb of the active states for untimed bisimulation equivalence, we must solve the following problem. For the timed bisimulation equivalence, we have only to consider the executable actions at the specified time instant (for example, the action \( a \) is executable at time 2, the action \( b \) is executable at time 3, \ldots). However, it is not the case for the untimed bisimulation equivalence. Consider the two A-TSLTSs in Fig. 4. If we consider the executability of actions at time \( d \) only, the states \( s_1 \) and \( s_3 \) should be untimed equivalent, because for duration \( d_1 = 2 \) after which only \( a \) is executable, there exists a duration \( d_2 = 3 \) after which only \( a \) is also executable, and vice versa. However, for the above example, \( s_1 \) and \( s_3 \) are not untimed equivalent in the sense of Definition 4, because after the delay of 2.5 units of time, \( s_1 \) is in the state such that only \( b \) is executable (after more 0.5 units of time elapsed), whereas \( s_3 \) is in the state such that only \( a \) is executable. So, instead of the executability at the given time instant, we consider the executability at some time after the given time instant. For the above example, when the system is at state \( s_1 \) and 2 units of time have elapsed, \( a \) is executable now and \( b \) is executable after more \( 3 - 2 = 1 \) unit of time elapses. In this case, \( s_1 \) is in the state such that both \( a \) and \( b \) are executable at some time in the future (see Fig. 5-(b)). In general, when \( d \) units of
time have elapsed and a is executable after more $d' - d$ units of time elapse, i.e., $d'$ satisfies both $d \leq d'$ and the transition condition of $a$, $a$ is executable at some time in the future.

Because of the reasons above, we must loose the executability condition of actions in order to define the mgb of the untimed bisimulation equivalence. So we define that for a given duration $d$, an action is executable if and only if there exists some duration $d'$ such that $d \leq d'$ and $d'$ satisfies the transition condition of the action. Note that $d'$, as well as $d$, must also satisfy the transition condition of the delay transition. Formally, let $P$ denote the transition condition of an action $a$. Then we say that the action $a$ is untimedly executable after duration $d$, if and only if $\exists d'[d \leq d' \land P(d'/d)]$. We refer to the condition as the untimed transition condition. Since we frequently consider the predicate of the form $\exists d'[d \leq d' \land P(d'/d)]$ w.r.t. $P$ and the variable $d$, we abbreviate it as $\mathcal{F}_d P$. Note that if the transition condition of the most recent delay transition is $D$, then $d$ ranges over the solutions of $D$. However, $\mathcal{F}_d P$ may have a solution $d'$ which does not satisfy $D$, which is incorrect. (Consider the untimed transition condition of $b$ in the sequence $s_0 \xrightarrow{e(d),d \leq 2} s_1 \xrightarrow{d,d=3} s_2$. In this case, the untimed transition condition becomes $\mathcal{F}_d\{P \land D\}$.

Using the untimed transition conditions, the mgb of the active states $(s_i, s_j)$ for untimed case is given as follows. Firstly, if $s_i$ and $s_j$ are untimed bisimulation equivalent w.r.t. an assignment $\rho$, for any action $a$ in a set $\text{Act}$ of all actions, the following condition holds. Suppose that the most recent delay transitions of $s_i$ and $s_j$ are $s_i \xrightarrow{e(d_i),D_{i}} s_i$ for some $s_{i_0}$, and $s_j \xrightarrow{e(d_j),D_{j}} s_j$ for some $s_{j_0}$, respectively. Note that the delay variable $d_i$ ($d_j$) ranges over solutions of the predicate $D_i$ ($D_j$, respectively). For any possible transition $s_i \xrightarrow{a,P_k}s_{i_k}$ whose untimed transition condition $\mathcal{F}_{d_i}[P_k \land D_i]$ satisfies $\rho \models \mathcal{F}_{d_i}[P_k \land D_i]$, if the action $a$ is untimely executable, there must exist some transition $s_j \xrightarrow{a,Q_{j},D_{j}} s_{j_i}$ whose untimed transition condition $\mathcal{F}_{d_j}[Q_{j} \land D_j]$ also satisfies $\rho \models \mathcal{F}_{d_j}[Q_{j} \land D_j]$ and the destinations $s_{i_k}$ and $s_{j_i}$ must be untimed bisimulation equivalent w.r.t. $\rho[d_i \rightarrow d'_i, d_j \rightarrow d'_j]$ ($\rho[d_i \rightarrow d'_i, d_j \rightarrow d'_j]$ must satisfy the mgb for $(s_{i_k}, s_{j_i})$). Here $\rho[d_i \rightarrow d'_i, d_j \rightarrow d'_j]$ denotes the same assignment as $\rho$ except the names of variables $d_i$ and $d_j$ are replaced with $d'_i$ and $d'_j$, respectively. Note that since it is
assumed that $a$ is untimely executed, the executed time of $a$ at the state $s_i$ is not $d_i$ but $d_i'$. So the destinations $s_{i_k}$ and $s_{j_l}$ can be reached with the values of not $d_i$ and $d_j$ but $d_i'$ and $d_j'$. That is why $s_{i_k}$ and $s_{j_l}$ must be untimed equivalent w.r.t. $\rho[d_i \rightarrow d_i', d_j \rightarrow d_j']$. The above discussions must be true when $s_i$ and $s_j$ are exchanged. Therefore, similar to the timed case, we obtain the mgb of active states $s_i$ and $s_j$ for untimed bisimulation equivalence as:

\[
\forall_{k\in K}\{F_{d_i}[P_k \land D_i] \Rightarrow \exists_{l\in L}\{F_{d_j}[Q_l \land D_j \land M_{k,l}\}]\}
\land \forall_{l\in L}\{F_{d_j}[Q_l \land D_j] \Rightarrow \exists_{k\in K}\{F_{d_i}[P_k \land D_i \land M_{k,l}\}\}\]

where, $K = \{k|s_i \xrightarrow{a_p} s_{i_k}\}$, $L = \{l|s_j \xrightarrow{a_q} s_{j_l}\}$, $M_{k,l} = mgb(s_{i_k}, s_{j_l})$, $s_{i_0} \xrightarrow{e(d_i), D_i} s_i$ for some $s_{i_0}$, and $s_{j_0} \xrightarrow{e(d_j), D_j} s_j$ for some $s_{j_0}$.

The functions $\text{match\_delay()}$ and $\text{match\_action()}$ can be modified properly for untimed bisimulation equivalence according to the mgb obtained above. Although, we omit the detailed definition for lack of space.

**Example 4** Consider the two A-TSLTSs in Fig 4. The mgb of $(s_1, s_3)$ for the untimed bisimulation equivalence can be obtained as follows:

\[
mgb(s_1, s_3) = \forall d_1[d_1 \leq 3 \Rightarrow \exists d_2[d_2 \leq 3 \land M_{24}]] \land \forall d_2[d_2 \leq 3 \Rightarrow \exists d_1[d_1 \leq 3 \land M_{24}]],
\]

where,

\[
M_{24} = \exists d_1'[d_1 \leq d_1' \land d_1' = 3 \land d_2 = 2 \Rightarrow \exists d_2'[d_2 \leq d_2' \land d_2' = 3 \land d_1' = 2 \land M_{00}]]
\land \exists d_2'[d_2 \leq d_2' \land d_2' = 3 \land d_2 = 3 \Rightarrow \exists d_1'[d_1 \leq d_1' \land d_1' = 2 \land M_{00}]]
\land \exists d_1'[d_1 \leq d_1' \land d_1' = 3 \land d_2 = 3 \Rightarrow \exists d_2'[d_2 \leq d_2' \land d_2' = 3 \land d_2 = 2 \land M_{00}]]
\land \exists d_2'[d_2 \leq d_2' \land d_2' = 3 \land d_1 = 2 \Rightarrow \exists d_1'[d_1 \leq d_1' \land d_1' = 3 \land M_{00}]],
\]

\[
M_{00} = \text{true}.
\]

After simplifying the above formula, we obtain $M_{24} \equiv (d_1 \leq 2 \land d_2 = 2) \lor (d_1 > 3 \land d_2 > 3)$. So we get $mgb(s_1, s_3) \equiv false$, that is, $s_1$ and $s_3$ are not untimed bisimulation equivalent.

\[\square\]

### 6 Conclusions

In this paper, we proposed a model A-TSLTS which can describe timed processes, and a verification method of timed verification equivalence for an A-TSLTS using a similar method as [1].

In contrast to other proposals for timed processes, our model allows arbitrary decidable 1st-order logic on any time domain for describing time constraints. In the model we can describe time constraints in a very flexible way and still we can verify timed bisimulation equivalence whose cost is independent of the absolute value of constants used in the time constraints. Although we do not handle value-passing in this paper, our model can easily be extended to the model with both time and value-passing by extending action transitions to have input/output values.
match\_delay(s_i, s_j, W) \overset{def}{=} if s_i \xrightarrow{e(d_i), P_i} s_{i'} and s_j \xrightarrow{e(d_j), P_j} s_{j'}

then let d = new(DVar(s_i) \cup DVar(s_j)), d' = new(DVar(s_i) \cup DVar(s_j) \cup \{d\}),

M_{i', j'} = match\_action(s_{i'}[d_i \rightarrow d], s_{j'}[d_j \rightarrow d'], W \cup \{(s_i, s_j)\}),

d, P_i\{d/d_i\}, d', P_j\{d'/d_j\}\) in

return \forall d[P_i\{d/d_i\} \Rightarrow \exists d'[P_j\{d'/d_j\} \wedge M_{i', j'}]]

\wedge \forall d'[P_j\{d'/d_j\}] \Rightarrow \exists d[P_i\{d/d_i\} \wedge M_{i', j'}]]

\mathrm{LOTS/T}\[2\]

\mathrm{match\_action}(s_i, s_j, W, d_i, d_j, D_j) \overset{def}{=} let \{K = \{k | s_i \xrightarrow{a_{P_k}} s_{i_k}\}, L = \{l | s_j \xrightarrow{a_{Q_l}} s_{j_l}\},

M_{k,l} = \mathrm{mb}(s_{i_k}, s_{j_l}, W \cup \{(s_i, s_j)\})\}

\wedge \forall d[P_k \wedge D_i \Rightarrow \exists d'[P_j\{d'/d_j\} \wedge M_{k,l}]]\}

\wedge \forall l \in L\{\forall d_j\{Q_l \wedge D_j \wedge M_{k,l}\}\}

\bigwedge_{k \in K}\{\mathcal{F}_d\{P_k \wedge D_i \Rightarrow \forall l \in L\{\forall d_j\{Q_l \wedge D_j \wedge M_{k,l}\}\}\}\}

where \mathcal{F}_d P \overset{def}{=} \exists d'[d \leq d' \wedge P[d'/d]]

Figure 6: Definition of \textit{match\_delay()} and \textit{match\_action()} for untimed bisimulation equivalence

Our method can be applicable to structural description languages of timed processes such as LOTOS/T[2]. To do that, we have only to provide a transformation from a description of a process to an A-TSLTS.

Our model has an expressive power of describing timing constraints by 1st-order formulas which contain some quantifiers. This might be too powerful for some applications. However, in [12], we have proposed a protocol synthesis method for LOTOS/T service specifications. In the method, derived protocol entity specifications generally contain existential quantifiers to express complicated timing dependencies among actions executed at different nodes. In such an application, our method becomes useful.

Our method is only applicable to the finite state A-TSLTS. For proving equivalence of non-finite-state timed processes, some axiomatic approaches such as [13] have been proposed. However, since untimed bisimulation equivalence is not congruence and the weakest congruence stronger than untimed bisimulation equivalence is equivalent to timed bisimulation equivalence[3, 4], an axiomatic approach for proving untimed bisimulation equivalence is unlikely. In this case, our method is still useful.

The question whether (time deterministic) A-TSLTSs are as expressive as (time deterministic) TSLTSs (modulo timed bisimulation equivalence) is left open.

The future works are to extend the result to the verification of timed weak bisimulation equivalence (internal actions are considered), and to implement the algorithm and evaluate the cost of the verification for practically large processes.
