EXPONENTIAL LIFTING AND HECKE CORRESPONDENCE

VALERI GRITSENKO

ABSTRACT. We give a review of some recent results related with Siegel modular forms with respect to the paramodular groups: Exponential Lifting (the infinite product construction), Symmetrisation, multiplicative Hecke correspondence. We give many new examples of modular forms and new constructions of some classical Siegel modular forms (f.e. of the Igusa modular forms of weight 35).

§1. OPERATORS OF SYMETRIZATION

In what follows we shall consider Siegel modular forms with respect to the paramodular group $\Gamma_t$ which is, by definition, an integral symplectic group of the skew-symmetric form with elementary divisors $(1, t)$. It can be realized as the following subgroup of $Sp_4(\mathbb{Q})$

$$\Gamma_t := \left\{ \begin{pmatrix} * & t & * & * \\ * & * & t^{-1} & * \\ t & * & * & * \\ * & * & * & * \end{pmatrix} \in Sp_4(\mathbb{Q}) \mid \text{all } \ast \text{ are integral} \right\}. $$

The quotient

$$A_t = \Gamma_t \backslash \mathbb{H}_2$$

is isomorphic to the coarse moduli space of Abelian surfaces with a polarization of type $(1, t)$ (see f.e. [Ig2]).

By $M_k(\Gamma_t, \chi)$ (resp. $\mathfrak{M}_k(\Gamma_t, \chi)$) we denote the space of all modular (resp. cusp) forms of weight $k$ with respect to the group $\Gamma_t$ with a character of finite order $\chi : \Gamma_t \rightarrow \mathbb{C}^*$. In [G2] we studied Hecke operators which transform modular forms with respect to $\Gamma_t$ into modular forms with respect to $\Gamma_{tp}$

$$Sym_{t,p} : M_k(\Gamma_t) \rightarrow M_k(\Gamma_{tp}), \quad Sym_{t,p} : F \mapsto \sum_{M \in (\Gamma_t \cap \Gamma_{tp}) \backslash \Gamma_{tp}} F|_k M.$$ 

We call this operator the operator of $p$-symmetrisation. It can be represented as an action of an element from the Hecke ring $H(\Gamma_{\infty,t})$ of the maximal parabolic subgroup $\Gamma_{\infty,t} \subset \Gamma_t$ which consists of elements fixing an isotropic line.

To see this, we take a system of representatives

$$(\Gamma_t \cap \Gamma_{tp}) \backslash \Gamma_{tp} = \{ J_{tp}, \nabla(\frac{b}{tp}), b \mod p \}$$
where

\[
J_t = \begin{pmatrix}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & t^{-1} \\
-1 & 0 & 1 & 0 \\
0 & -t & 0 & 0
\end{pmatrix}, \quad \nabla(a) = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 0
\end{pmatrix}.
\]

It is valid \(J_t J_{tp} = \text{diag}(1, p, 1, p^{-1})\), thus for any \(F \in \mathfrak{M}_{k}(\Gamma_t)\) we have

\[
\text{Sym}_{t,p}(F) = F|_k(\Lambda_p + \sum_{b \mod p} \nabla(b)).
\]

The last operator is defined by the following element in the Hecke ring of the maximal parabolic subgroup \(\Gamma_{\infty,t}\) of \(\Gamma_t\).

\[
\text{Sym}_p = \Lambda_p + \nabla_{t,p} \in H(\Gamma_{\infty,t}), \quad \text{where} \quad \nabla_{t,p} = \sum_{b \mod p} \Gamma_{\infty,t} \nabla(b)
\]

and \(\Lambda_p = \Gamma_{\infty,t} \text{diag}(p, 1, p^{-1}, 1)\). Using this description of the \(p\)-symmetrisation as a Hecke operator in the parabolic extension of the Hecke ring (i.e., in the Hecke ring of a maximal parabolic subgroup, see [G2], [G6]–[G7], [G10] for the theory of such rings) we proved

**Theorem of Injectivity.** (see [G2]) The operator of \(p\)-symmetrisation is injective if \((t, p) = 1\).

This theorem has the following application in algebraic geometry.

**Corollary 2.** Let \(\bar{\mathcal{A}}_t\) be a smooth compactification of the moduli space of \((1, t)\)-polarized Abelian surfaces, then for arbitrary divisor \(d\) of \(t\) the operator of symmetrisation defines an embedding of the spaces of the canonical differential forms

\[
\text{Sym} : H^{3,0}(\bar{\mathcal{A}}_d) \to H^{3,0}(\bar{\mathcal{A}}_t).
\]

In particular the inequality between the Hodge numbers of Siegel threefolds is valid

\[
h^{3,0}(\bar{\mathcal{A}}_t) \geq h^{3,0}(\bar{\mathcal{A}}_d).
\]

We recall that an estimation from below for the geometric genus \(h^{3,0}(\mathcal{A}_t)\) of the moduli space \(\mathcal{A}_t\) was obtained in [G1] and [G4]:

\[
h^{3,0}(\mathcal{A}_t) \geq \dim J_{3,t}^{\text{cusp}}
\]

where \(J_{3,t}^{\text{cusp}}\) is the space of Jacobi cusp forms of weight 3 and index \(t\). The elements from \(H^{3,0}(\mathcal{A}_t)\) are constructed using an arithmetic lifting, which is a generalization of the Maass lifting. We recall now the corresponding construction.

Let

\[
\phi(r, z) \in J_{k,t}^{\text{cusp}}
\]
be a Jacobi cusp form of weight \( k \) and index \( t \). By definition \( \tilde{\phi}(Z) = \phi(\tau, z) \exp(2\pi i t \omega) \) where \( Z = \begin{pmatrix} \tau & z \\ z & \omega \end{pmatrix} \in \mathbb{H}_2 \). Let

\[
T_{-}(m) = \sum_{\substack{ad = m \\ b \mod d}} \Gamma_{\infty} \begin{pmatrix} a & 0 & b & 0 \\ 0 & m & 0 & 0 \\ 0 & 0 & d & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \in H(\Gamma_{\infty}),
\]

where \( \Gamma_{\infty} \subset Sp_{4}(\mathbb{Z}) \) is the maximal parabolic subgroup of parabolic rank one, be an element of the Hecke ring of the parabolic subgroup \( \Gamma_{\infty} \). Then we have the following result

**Arithmetic Lifting Theorem.** (see [G1], [G4]–[G5]). Let \( \phi \) be as above. Then

\[
\text{Lift}(\phi)(Z) = \sum_{m=1}^{\infty} m^{2-k} (\tilde{\phi}|_{k} T_{-}(m))(Z) \in \mathfrak{M}_{k}(\Gamma_{t})
\]

is a cusp form of weight \( k \) with respect to the paramodular group \( \Gamma_{t} \).

The Rankin-Selberg convolution related with these modular forms is equal to the Spin (Andrianov) \( L \)-function of Siegel modular forms. In this way one can get a very short and clear construction of analytic continuation (together with the functional equation) of Spin-\( L \)-function (see [G3]).

The arithmetic lifting commutes with operator of \( p \)-symmetrisation

\[
\text{Sym}_{t,p}(\text{Lift}(\phi)) = p^{3-k} \text{Lift}(\phi|_{k} T_{-}(p)).
\]

(see Satz 2.10 and Satz 3.1 in [G2]).

Let us define the multiplicative analogue of the \( p \)-symmetrisation.

**Definition of Multiplicative Symmetrisation.** Let \( F \in \mathfrak{M}_{k}(\Gamma_{t}, \chi) \) be a modular form of weight \( k \in \mathbb{Z}/2 \) with respect to the paramodular group \( \Gamma_{t} \) with a character (or a multiplier system) \( \chi : \Gamma_{t} \rightarrow \mathbb{C}^{*} \). Then for a prime \( p \) we define the operator of multiplicative symmetrisation

\[
\text{Ms}_{p} : F \mapsto p^{-k} \overline{\chi}(J_{t}) \prod_{M_{t} \in \Gamma_{t} \cap \Gamma_{tp}} F|_{k} M_{t}.
\]

(The additional constant \( p^{-k} \overline{\chi}(J_{t}) \) makes formulae simpler.)

It is clear that the result of the multiplicative symmetrisation is a modular form of weight \( k(p+1) \)

\[
\text{Ms}_{p}(F) \in \mathfrak{M}_{k(p+1)}(\Gamma_{tp}, \chi^{(p)})
\]

where \( \chi^{(p)} \) is a character of \( \Gamma_{tp} \). Moreover if the modular form \( F \) is zero along a Humbert surface \( H_{t} \subset A_{t} \) of discriminant \( D \), then \( \text{Ms}_{p}(F) \) is zero along \( \text{Ms}_{p}^{(p)}(H_{t}) \) which is a sum (with some multiplicities) of Humbert surfaces with discriminant \( D \) and \( p^{2}D \) in \( A_{tp} \) (for the definition of Humbert surfaces see the next section). We remark that the operators of symmetrisation and multiplicative symmetrisation were used (in particular case \( p = 2 \)) in the paper of Freitag [F] in 1967.
§2. EXPONENTIAL LIFTING

In this section we describe a construction which gives us modular forms with divisor equals to a union of Humbert surfaces. For our purpose it is more convenient to consider Humbert surfaces as divisors of a double cover of the moduli space of $(1, t)$-polarized Abelian surfaces $A_t$. To define this covering we consider a double normal extension of the paramodular group $\Gamma_t$

$$\Gamma_t^+ = \Gamma_t \cup \Gamma_t V_t, \quad V_t = \frac{1}{\sqrt{t}} \left( \begin{array}{cc} 0 & t \\ 1 & 0 \\ 0 & 0 \\ 0 & 0 \end{array} \right).$$

The double quotient

$$A_t \to A_t^+ = \Gamma_t^+ \backslash \mathbb{H}^2$$

of $A_t$ can be interpreted as a moduli space of lattice-polarized $K3$ surfaces for arbitrary $t$ or as the moduli space of Kummer surfaces of $(1, p)$-polarized Abelian surfaces for a prime $t = p$ (see [GH, Theorem 1.5]).

Any Humbert surface in $A_t^+$ of discriminant $D$ can be represented in the form

$$H_D^t(b) = \pi_t^+ \left( \bigcup_{g \in \Gamma_t^+} g^*(\{Z \in \mathbb{H}_2 | a\tau + bz + tw = 0\}) \right)$$

where $a, b \in \mathbb{Z}, D = b^2 - 4ta$, $b \mod 2t$ and $\pi_t^+: \mathbb{H}_2 \to A_t^+$ (see [vdG], [GH]). Remark that $H_D^t(b)$ depends only on $\pm b \mod 2t$.

The datum for the exponential lifting is a nearly-holomorphic Jacobi form

$$\phi_{0,t}(\tau, z) = \sum_{n, l \in \mathbb{Z}} f(n, l) q^n r^l \in J_{0,t}^{nh}$$

of weight 0 and index $t$. Nearly holomorphic means that there exist a number $m$ such that $\Delta^m(\tau) \phi(\tau, z)$ is a weak Jacobi form. If we chose the minimal non-negative $m$ with this property then $n \geq -m$ in the Fourier expansion (2.1). We recall the notations

$$q = \exp(2\pi i \tau), \quad r = \exp(2\pi i z), \quad s = \exp(2\pi i \omega), \quad Z = \begin{pmatrix} \tau & z \\ z & \omega \end{pmatrix} \in \mathbb{H}_2$$

and $\widetilde{\phi}_{0,t}(Z) = \phi_{0,t}(\tau, z) \exp(2\pi il \omega)$. Let

$$\phi_{0,t}^{(0)}(z) = \sum_{l \in \mathbb{Z}} f(0, l) r^l$$

be the $q^0$-part of $\phi_{0,t}(\tau, z)$. The Fourier coefficient $f(n, l)$ of $\phi_{0,t}$ depends only on the norm $4tn - l^2$ of $(n, l)$ and $l \mod 2t$. From the definition of nearly holomorphic forms, it follows that the norm of indices of non-zero Fourier coefficients are bounded from bellow. One can prove the following theorem which gives us a construction of Siegel modular forms as infinity products (compare with Borcherds construction in [B]).
Exponential Lifting Theorem. (see [GN6], [GN1]) Assume that the Fourier coefficients of Jacobi form $\phi_{0,t}$ from (2.1) are integral. Then the product

$$\text{Exp-Lift}(\phi_{0,t})(Z) = B_{\phi}(z) = q^{A}r^{B} s^{C} \prod_{n,l,m \in \mathbb{Z}} (1 - q^{n}r^{l}s^{m})^{f(nm,l)}, \quad (2.3)$$

where

$$A = \frac{1}{24} \sum_{l} f(0, l), \quad B = \frac{1}{2} \sum_{l > 0} lf(0, l), \quad C = \frac{1}{4} \sum_{l} l^{2} f(0, l),$$

and $(n,l,m) > 0$ means that if $m > 0$, then $l$ and $n$ are arbitrary integers, if $m = 0$, then $n > 0$ and $l \in \mathbb{Z}$ or $l < 0$ if $n = m = 0$, defines a meromorphic modular form of weight $\frac{f(0,0)}{2}$ with respect to $\Gamma_{t}^{+}$ with a character (or a multiplier system if the weight is half-integral) induced by $v_{\eta}^{24A} \times v_{H}^{2B}$. All divisors of $\text{Exp-Lift}(\phi_{0,t})(Z)$ on $A_{t}^{+}$ are the Humbert modular surfaces $H_{D}(b)$ of discriminant $D = b^{2} - 4ta$ with multiplicities

$$m_{D,b} = \sum_{n > 0} f(na^{2}, nb).$$

Moreover

$$B_{\phi}(V_{t}(Z)) = (-1)^{D} B_{\phi}(Z) \quad \text{with} \quad D = \sum_{n < 0 \atop l \in \mathbb{Z}} \sigma_{1}(-n) f(n, l)$$

where $\sigma_{1}(n) = \sum_{d \mid n} d$.

The infinite product expansion of modular form $\Delta_{5}(Z)$. (see [GN1]–[GN2]). We recall that there exists the unique, up to a constant, weak Jacobi form of weight zero and index one

$$\phi_{0,1}(\tau, z) = \frac{\phi_{12,1}(\tau, z)}{\eta(\tau)^{24}} = \sum_{n \geq 0, l} f_{1}n, l q^{n} r^{l} \left( r + 10 + r^{-1} \right) + q(10r^{-2} - 64r^{-1} + 108 - 64r + 10r^{2}) + q^{2}(\ldots)$$

where $\phi_{12,1}$ is the unique Jacobi cusp form of weight 12 and index 1 with integral coprime coefficients. There are several formulae for Fourier coefficients of this Jacobi form. In [EZ] one can find a formula for Fourier coefficients of $\phi_{12,1}$ in it terms of Cohen’s numbers (values of special $L$-functions at integral points)

$$\phi_{12,1}(\tau, z) = 12^{-2} (E_{4}^{2}(\tau) E_{4,1}(\tau, z) - E_{6}(\tau) E_{6,1}(\tau, z)).$$

For a very convenient formula in terms of Hecke operators see (3.7)–(3.9) below. Let us consider the product of even theta-constants

$$\Delta_{5}(Z) = 2^{-6} \prod_{a,b} \Theta_{a,b}(Z) \in \mathfrak{M}_{5}(Sp_{4}(Z), \chi_{2})$$

where $\Theta_{a,b}(Z) = \sum_{\substack{m,n \in \mathbb{Z} \atop m,n \equiv 0 \pmod{2}}} \Theta_{a,b}(m,n) Z^{m} \bar{Z}^{n}$.
which is a cusp form of weight 5 with non-trivial binary character of $Sp_4(Z)$. The square of $\Delta_5(Z)$ is the first Siegel cusp form of weight 10 (see [Ig1]). Using the exponential lifting for the function $\phi_{0,1}$ we get the following result from [GN1]

$$\Delta_5(Z) = (qrs)^{1/2} \prod_{n,l,m \in \mathbb{Z}} \left(1 - q^n r^l s^m\right) f_1(nm, l) \in \mathfrak{g}_5(\Gamma_1, \chi_2) \quad (2.4)$$

where $f_1(n, l)$ are the Fourier coefficients of $\phi_{0,1}(\tau, z)$.

The general explanation of the existence of such infinite product expansion is the fact the modular form $\Delta_5$ defines a generalized Lorentzian Kac–Moody super-algebra (see [GN1]).

Siegel theta-constant. Let us consider the “most odd” even Siegel theta-constant $\Theta_{1,1}(Z) = \frac{1}{2} \sum_{l_1, l_2 \in \mathbb{Z}} \exp(\pi i (Z[l_1^2-l_2^2]\pm l_1 + l_2)) = \frac{1}{2} \sum_{n,m \in \mathbb{Z}} \left(\frac{-4}{n}\right)\left(\frac{-4}{m}\right) q^{n^2/8} r^{nm/4} s^{m^2/8}$, where $Z[M] = {}^tMZM$. One can prove that the function

$$\Delta_{1/2}(\begin{pmatrix} \tau \\ z \\ \omega \end{pmatrix}) = \Theta_{1,1}(\begin{pmatrix} \tau \\ 2z \\ 4\omega \end{pmatrix}) \in \mathfrak{g}_1(\Gamma_4, \chi_8)$$

is a modular form of weight 1/2 with respect to the paramodular group $\Gamma_4$ with a multiplier system of order 8 (see [GN6]). The first non-zero Fourier-Jacobi coefficient of $\Delta_{1/2}$ is the Jacobi theta-series

$$\vartheta(\tau, z) = \sum_{n \equiv \frac{1}{2} \mod 2} (-1)^{n-1} \exp\left(\frac{\pi i n^2}{4} \tau + \pi i nz\right) = \sum_{m \in \mathbb{Z}} \left(\frac{-4}{m}\right) q^{m^2/8} r^{m/2}$$

or, equivalently,

$$\vartheta(\tau, z) = -q^{1/8} r^{-1/2} \prod_{n \geq 1} (1 - q^{n-1} r)(1 - q^n r^{-1})(1 - q^n). \quad (2.5)$$

We can define a weak Jacobi form

$$\phi_{0,4}(\tau, z) = \frac{\vartheta(\tau, 3z)}{\vartheta(\tau, z)} = \sum_{n \geq 0, l \in \mathbb{Z}} f_4(n, l) q^n r^l$$

$$= r^{-1} \prod_{m \geq 1} \left(1 + q^{m-r} + q^{2m-r^2}\right) \prod_{n \equiv 1,2 \mod 3} \left(1 - q^n r^3\right) \prod_{n \geq 1} \left(1 - q^n r^{-3}\right)$$

$$= (r + 1 + r^{-1}) - q(r^4 + r^3 - r + 2 - r^{-1} + r^{-3} + r^{-4}) + q^2(\ldots) \quad (2.6)$$

where all Fourier coefficients $f_4(n, l)$ of the weak Jacobi form are integral (in fact they are Fourier coefficients of automorphic forms of weight $-1/2$). Thus according to Exponential Lifting Theorem $\text{Exp-Lift}(\phi_{0,4})$ is a modular form of weight 1/2 with respect to the paramodular group $\Gamma_4^+$ having irreducible Humbert modular surface $H_1$ as its divisor. One can show that the quotient $\Delta_{1/2}(Z)/\text{Exp-Lift}(\phi_{0,4})(Z)$ is a holomorphic automorphic function invariant with respect to $\Gamma_4^+$, thus it is a constant and we get the following infinite product expansion of $\Delta_{1/2}(Z)$:

$$\frac{1}{2} \sum_{n,m \in \mathbb{Z}} \left(\frac{-4}{n}\right)\left(\frac{-4}{m}\right) q^{n^2/8} r^{nm/2} s^{m^2/2} = q^{1/8} r^{1/2} s^{1/2} \prod_{(n,l,m) > 0} (1 - q^n r^l s^{4m}) f_4(nm, l).$$
Modular forms $\Delta_1(Z)$ and $\Delta_2(Z)$. Let us define two weak Jacobi forms of weight 0

$$\phi_{0,2}(\tau, z) = \frac{1}{2} \eta(\tau) - 4 \sum_{m, n \in \mathbb{Z}} (\frac{-4}{m}) (\frac{12}{n}) q^{\frac{3m^2+n^2}{24}} r^{\frac{m+n}{2}} = \sum_{n \geq 0, l \in \mathbb{Z}} f_{2(n, l)} \eta(q^r)$$

(2.7)

($r^l$ means that we have two summands with $r^l$ and with $r^{-l}$) and

$$\phi_{0,3}(\tau, z) = (\frac{\theta_{3/2}(\tau, z)}{\eta(\tau)})^2 = \sum_{n \geq 0, l \in \mathbb{Z}} f_{3(n, l)} q^{nl} r = r^{-1} \prod_{n \geq 1} (1+q^{n-1}r)(1+q^{n}r^{-1})(1-q^{2n-1}r)2(1-q-1-2)2n)^2 r$$

(2.8)

of index 2 and 3 respectively. Their Fourier coefficients satisfy the property: if $4tn - l^2 < 0$ and $f_t(n, l) \neq 0$, then $4tn - l^2 = -1$ and $f_t(n, l) = 1$.

According to Exponential Lifting Theorem Exp-Lift($\phi_{0,3}$) is a modular form of weight 1 with respect to $\Gamma_3$ with a character of order 6 and Exp-Lift($\phi_{0,2}$) is a modular form of weight 2 with respect to $\Gamma_2$ with a character of order 4. One can calculate the Fourier expansion of these modular forms. It turns out that (see [GN6])

$$\Delta_1(Z) = \sum_{M \geq 1} \sum_{n, m \equiv 1 \mod 6 \atop 4nm-3t^2=M^2} (\frac{-4}{M}) (\frac{12}{n}) \sum_{a | (n, l, m)} \frac{6}{a} q^{n/6} r^{l/2} s^{m/2}$$

$$= q^{\frac{1}{6}} r^{\frac{1}{3}} s^{\frac{1}{2}} \prod_{n, l, m \in \mathbb{Z}} \frac{1}{(n, l, m) > 0} (1-q^{n}r^{l} s^{3m}) f_3(nm, l) \in \mathfrak{M}_1^{\text{cusp}}(\Gamma_3^+, \chi_6)$$

where the character $\chi_6 : \Gamma_3^+ \to \sqrt[6]{1}$ is induced by $v^4 \times v_H$ and

$$\Delta_2(Z) = \sum_{N \geq 1} \sum_{n, m \equiv 1 \mod 4 \atop 2nm-3t^2=N^2} N \left(\frac{-4}{Nl}\right) \sum_{a | (n, l, m)} \left(\frac{-4}{a}\right) q^{n/4} r^{l/2} s^{m/2}$$

$$= q^{\frac{1}{6}} r^{\frac{1}{3}} s^{\frac{1}{2}} \prod_{n, l, m \in \mathbb{Z}} \frac{1}{(n, l, m) > 0} (1-q^{n}r^{l} s^{3m}) f_2(nm, l) \in \mathfrak{M}_2^{\text{cusp}}(\Gamma_2^+, \chi_4)$$

where $\chi_4 : \Gamma_2^+ \to \{\sqrt[4]{1}\}$. Moreover the divisor of these modular forms is the irreducible Humbert surface $H_1$

$$\text{Div}_{A_3^+}(\Delta_1(Z)) = H_1, \quad \text{Div}_{A_2^+}(\Delta_2(Z)) = H_1.$$
These modular forms are discriminant of the moduli space of special $K3$ surfaces (see [GN3]). One can prove also that $\Delta_1^3$ and $\Delta_2^3$ are the cusp forms of the minimal weights with respect to $\Gamma_3$ and $\Gamma_2$ respectively. Using information about divisors of these modular forms one can easily prove the rationality of the moduli space of Kummer surfaces $A^+_t = \Gamma^+_t \setminus \mathbb{H}_2$ associated with $(1, 2)$- and $(1, 3)$-polarized Abelian surfaces.

Similar to the arithmetic lifting and the $p$-symmetrisation (1.4), the exponential lifting commutes with the multiplicative symmetrisation $M_s$ (see (1.5)).

Theorem. Let $\phi \in J_{0,t}^{nh}$ be like in Exponential Lifting Theorem. Then for an arbitrary prime $p$ we have

$$M_s(\text{Exp-Lift}(\phi_{0,t})) = \text{Exp-Lift}(\phi_{0,t}|\tau_-(p)).$$

Proof. We give a proof of this theorem to illustrate the methods we use and to clarify the exponential lifting construction.

Firstly we use the following special representation of the exponential lifting. Let us decompose the product of the exponential lifting in two factors

$$B_\phi(Z) = q^{A_B s C} \prod_{(n,l,0) > 0} (1 - q^n r^l) f^{(0,l)} \times \prod_{n,l,m \in \mathbb{Z} m > 0} (1 - q^n r^l s^{tm}) f^{(nm,l)} \quad (2.9)$$

and let us calculate the Fourier expansion of the logarithm of the second factor:

$$\log \left( \prod_{n,l,m \in \mathbb{Z} m > 0} (1 - q^n r^l s^{tm}) f^{(nm,l)} \right) = - \sum_{n,l \in \mathbb{Z}, m > 0} f^{(nm,l)} \sum_{e \geq 1} \frac{1}{e} q^{en r^e s^{emt}}$$

$$= - \sum_{a,b,c \in \mathbb{Z}} \sum_{d | (a,b,c)} \sum_{c > 0} d^{-1} f(\frac{ac}{d^2}, \frac{b}{d}) q^{a r^b s^c}.$$

Like in Arithmetic Lifting Theorem the last sum can be written as the action of the formal Dirichlet series (a formal Hecke $L$-function of $SL_2(Z) \sum_{m \geq 1} m^{-1} T_-(m)$ on the Jacobi form $\phi_{0,t}$ where $T_-(m)$ (see (1.2)) are Hecke elements from the Hecke ring of the parabolic subgroup, Thus we obtain

$$\log \left( \prod_{n,l,m \in \mathbb{Z} m > 0} \ldots \right) = - \sum_{m \geq 1} m^{-1} (\phi_{0,t} | T_-(m))(Z).$$

This expansion shows us that the second factor in (2.9) is invariant with respect to the action of the parabolic subgroup $\Gamma_{\infty,t}$ whenever the product converges.

It is easy to see that the first factor in (2.9) is equal to a product of Jacobi theta-series and Dedekind eta-functions

$$q^{A_B s C} \prod_{(n,l,0) > 0} (1 - q^n r^l) f^{(0,l)} = \eta(\tau) f^{(0,0)} \prod_{l \geq 0} \left( \frac{\eta(\tau l^2) e^{\pi i l^2 \omega}}{\eta(\tau)} \right) f^{(0,l)}.$$
The last identity explains the form of the factor $q^{A}r^{B}s^{C}$ in the definition of the function of the theorem. Thus we proved that

$$q^{A}r^{B}s^{C} \prod_{n,l,m \in \mathbb{Z} \atop (n,l,m) > 0} (1 - q^{n}r^{l}s^{m}) f(nm, l)$$

$$= \eta(\tau) f(0,0) \prod_{i > 0} \left( \frac{\vartheta(\tau, i\omega) e^{\pi i l\omega}}{\eta(\tau)} \right)^{f(0, l)} \exp \left( - \sum_{m \geq 1} m^{-1} \bar{\phi}_{0,t}(m) |T_{-}(m)(Z)| \right)$$

(2.10)

whenever the product converges. Thus $B_{\phi}(Z)$ transforms like a $\Gamma_{\infty,t}$-modular form of weight $\frac{f(0,0)}{2}$ with the multiplier system of the theorem. It is useful to write down the whole product $B_{\phi}(Z)$ in terms of Hecke operators $T_{-}(m)$. We can get such expression using the involution $V_{t}$

$$\text{Exp-Lift}(\phi_{0,t})(Z) = B_{\phi}(Z) =$$

$$= q^{A}r^{B}s^{C} \exp \left( - \sum_{m \geq 1} m^{-1} \bar{\phi}_{0,t}(m) |T_{-}(m)(Z)| \right) \exp \left( - \sum_{m \geq 1} m^{-1} (\bar{\phi}_{0,t}^{(0)} + \phi_{0,t}^{(0)}) |T_{-}(m)| V_{t}(Z) \right).$$

(2.11)

The functions $\phi_{0,t}^{(0)}(z) = \sum_{i \geq 0} f(0, l)r^{l}$ and $\bar{\phi}_{0,t}^{(0)}(Z) = \sum_{i \geq 0} f(0, l)r^{l}s^{t}$ are not Jacobi forms, and we fix the standard system of representatives in $T_{-}(m)$ to define the corresponding formal action. The exponent of the function $\bar{\phi}_{0,t}^{(0)}$ in (2.11) defines the subproduct over all $(n, l, 0)$ with $n > 0$ in (2.9). The exponent with the function $\phi_{0,t}^{(0)}$, which does not depend on $\tau$ and $\omega$, defines the finite subproduct over $(0, l, 0)$ with $l > 0$. The representation (2.11) shows us analogy between the exponential lifting and the arithmetic lifting of holomorphic Jacobi forms.

The formula for the multiplicative symmetrisation (see (1.5))

$$\text{Ms}_{p}(F)(Z) = F\left( \tau, \frac{p\tau}{p^{2}\omega} \right) \prod_{b \mod p} F\left( \tau, \frac{z}{p} + \frac{b}{p^{2}} \right) \in M_{k(p+1)}(\Gamma_{t}, \chi^{(p)})$$

shows that $\text{Ms}_{p}$ can be written as the action of $\text{Sym}_{p}$ on the function under the exponent in (2.11). Let us consider the product of the formal Dirichlet series $\sum_{m=1}^{\infty} T_{-}(m)m^{-1}$ over the Hecke ring $H(\Gamma_{\infty,t})$ with $\text{Sym}_{p} = \Lambda_{p} + \nabla_{t,p}$. According to the definition of the normalizing factor of Hecke operators in the case of weight zero, we can consider the Hecke ring $H(\Gamma_{\infty,t})$ modulo its central element $\Delta(p) = \Gamma_{\infty,t}(pE_{4})$. I.e. for any $X \in H(\Gamma_{\infty,t})$ the Hecke operators $X$ and $\Delta(p)X$ are identical. We recall that $\Delta(p)\Lambda_{p} = T_{-}(p, p)$ where $T_{-}(p, p)$ is the embedding of $T(p, p) = SL_{2}(\mathbb{Z})(pE_{2})SL_{2}(\mathbb{Z}) \in H(SL_{2}(\mathbb{Z}))$ into the Hecke ring $H(\Gamma_{\infty,t})$. Using the definition one can check that

$$T_{-}(m)\nabla_{t,p} = \begin{cases} pT_{-}(m) & \text{if } m \equiv 0 \mod p \\ \nabla_{t,p} T_{-}(m) & \text{if } m \not\equiv 0 \mod p. \end{cases}$$
Thus
\[
\left(\sum_{m=1}^{\infty} T_{-}(m) m^{-1}\right)\left(T_{-}(p, p) + \nabla_{t, p}\right)
= \sum_{m \geq 1} \left(T_{-}(mp) + pT_{-}\left(\frac{m}{p}\right) T_{-}(p, p)\right) m^{-1} + \sum_{(m, p) = 1} \nabla_{t, p} T_{-}(m) m^{-1}
= T_{-}(p) \sum_{m \geq 1} T_{-}(m) m^{-1} + \nabla_{t, p} \cdot \sum_{(m, p) = 1} T_{-}(m) m^{-1}, \quad (2.12)
\]
since \(T(m)T(p) = T(mp) + pT(p, p)T\left(\frac{m}{p}\right)\) in \(H(SL_2(\mathbb{Z}))\).

Let us consider the representation (2.11) for the exponential lifting of \(\phi_{0,t}\). According to (2.12) we have the following identity for the main factor in (2.11)

\[
\exp\left(-\sum_{m \geq 1} (\bar{\phi}_{0,t}|T_{-}(m))\right)\mathrm{Sym}_p(Z) = \exp\left(-\sum_{m \geq 1} (\bar{\phi}_{0,t}|T_{-}(p))\right)\mathrm{Sym}_p(Z),
\]
since \(\nabla_{t, p}\) defines zero operator on the space of Jacobi functions of weight 0 and index \(t\):

\[
(\bar{\phi}_{0,t}|\nabla_{t, p})(Z) = \bar{\phi}_{0,t}(Z) \cdot \sum_{b \bmod p} \exp\left(\frac{2\pi ib}{p}\right) = 0.
\]

Let us consider the second exponent in (2.11). We have the formal identity

\[
V_{t} \left(\Lambda_{p} + \sum_{b \bmod p} \nabla\left(\frac{b}{tp}\right)\right) = T_{-}(p)V_{t}(\sqrt{p}E_{4})^{-1}
\]
where we consider \(T_{-}(p)\) as the formal sum of the left cosets fixed in (1.2) and \(V_{t}\) is the involution defined in the beginning of this section. The second exponent in (2.11) is not \(\Gamma_{\infty, t}\)-invariant, but it is invariant with respect to the minimal parabolic subgroup \(\Gamma_{00}\) which is the intersection of \(\Gamma_{\infty, t}\) with the subgroup of the upper-triangular matrices in \(\Gamma_{t}\). This parabolic subgroup is the semidirect product of the subgroup of all upper-triangular matrices in \(SL_2(\mathbb{Z})\) with the Heisenberg group. Thus we still can consider \(T_{-}(m)\) as an element of the Hecke ring \(H(\Gamma_{00})\) of this minimal parabolic subgroup if we take \(T_{-}(m)\) in the standard form (1.2). (See [G9], where Hecke rings of parabolic subgroups of this type were considered for \(GL_n\) over a local field.) Thus for the second exponent in (2.11) we get

\[
\exp\left(-\sum_{m \geq 1} m^{-1}(\bar{\phi}_{0,t}^0 + \phi_{0,t}^0)|T_{-}(m))V_{t}|\mathrm{Sym}_p(Z)\right)
= \exp\left(-\sum_{m \geq 1} m^{-1}(\bar{\phi}_{0,t}^0 + \phi_{0,t}^0)|T_{-}(p)|T_{-}(m))V_{t}|(Z)\right).
\]

This finishes the proof.
\[\square\]

Many examples of using the multiplicative symmetrisation see in [GN6].
§3. Multiplicative Hecke Operators

Let \( F \in \mathcal{M}_k(\Gamma_t, \chi) \) be a modular form of integral weight and

\[
X = \Gamma_t M \Gamma_t = \sum_i \Gamma_t g_i \in \mathcal{H}_*(\Gamma_t) = \bigotimes_{(p,t)=1} \mathcal{H}_p(\Gamma_t)
\]

be a Hecke element with a good reduction modulo all primes dividing \( t \). Then we can define a multiplicative Hecke operator

\[ [F]_X := \prod_i F|_{k g_i}. \tag{3.1} \]

This is again a \( \Gamma_t \)-modular form. We call it the Hecke product of \( F \) defined by \( X \).

It is well known that the arithmetic lifting (1.3) commutes with the action of Hecke operators (see f.e. [G2], [G8]). In Theorem A.7 of [GN4, Appendix A] we proved that the exponential lifting commutes with multiplicative Hecke operators. More exactly we have

**Functoriality of Exponential Lifting.** For arbitrary \( \phi \in J_{0,t}^{nh} \) and \( X \in \mathcal{H}_*(\Gamma_t) \) the identity

\[ [\text{Exp-Lift}(\phi)]_X = c \cdot \text{Exp-Lift}(\phi|_{J(t)}(X)) \tag{3.2} \]

is valid, where \( J_0(t) \) is a natural projection of the Hecke ring \( \mathcal{H}_*(\Gamma_t) \) into the Hecke-Jacobi ring of the parabolic subgroup of \( \Gamma_t \) (see [G2], [G6], [G8]) and \( c \) is a constant.

**Remark.** The operator \( J_0(t) \) is the same one which appears in the commutative relation between the arithmetic lifting and Hecke operators (see [G8]).

To prove this theorem one should use only some considerations related with parabolic extension of local Hecke rings, similar to the proof of the commutativity of the exponential lifting with multiplicative symmetrisation.

We consider below some examples related with the Hecke operator of index \( p \) \( T(p) = \Gamma_t \text{diag}(1,1,p,p) \Gamma_t \) in the case of good and bad reduction. If \( T(p) \in H(\Gamma_t) \) \( (p,t)=1 \) we have

\[
T(p) = \Gamma_t \left( \begin{array}{cccc} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right) + \sum_{a_1,a_2,a_3 \mod p} \Gamma_t \left( \begin{array}{cccc} 1 & 0 & a_1 & a_2 \\ 0 & 1 & a_2 & a_3/t \end{array} \right) \left( \begin{array}{cccc} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & p \\ 0 & 0 & 0 & p \end{array} \right)
\]

\[
+ \sum_{a \mod p} \Gamma_t \left( \begin{array}{cccc} 1 & 0 & a & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \end{array} \right) + \sum_{b_1,b_2 \mod p} \Gamma_t \left( \begin{array}{cccc} -b_1 & 1 & 0 & b_2/t \\ 0 & 0 & 1 & b_1 \\ 0 & 0 & 0 & p \end{array} \right) \tag{3.3} \]

and

\[ J_0(T(p)) = T_0(p) + p^2 + p \tag{3.4} \]

where \( T_0(p) \) is the Hecke-Jacobi operator

\[
T_0(p) = \sum_{b \mod p} \Gamma_{\infty} \left( \begin{array}{cccc} 1 & 0 & c & b \\ 0 & p & 0 & 0 \\ 0 & 0 & p & 0 \\ 0 & 0 & 0 & p \end{array} \right) + \sum_{a,b \mod p} \Gamma_{\infty} \left( \begin{array}{cccc} p & 0 & a & ab \\ 0 & p & 0 & ab/b^2 \\ 0 & 0 & p & 0 \\ 0 & 0 & 0 & p \end{array} \right) + \sum_{\lambda \mod p} \Gamma_{\infty} \left( \begin{array}{cccc} p^2 & 0 & 0 & 0 \\ 0 & p & 0 & 0 \end{array} \right). \tag{3.5} \]
The element $T_0(p)$ defines an operator on the space of Jacobi forms which does not change the index

$$T_0(p) : J_{k,t} \to J_{k,t}.$$  

It coincides (up to a constant) with the Hecke operator $T_p$ defined in [EZ, §4].

We want to use (3.2) with $X = T(p)$ for the modular forms $\Delta_5(Z)$, $\Delta_2(Z)$, $\Delta_1(Z)$ and $\Delta_{1/2}(Z)$ from §2. To write down the right hand side of (3.2), we need a formula for the action of $T_0(p)$ on the Jacobi forms of index $t$ for a divisor $p$ of $t$. Let $\phi_{0,t}(\tau, z)$ be an arbitrary Jacobi form of weight zero and index $t$ with Fourier expansion

$$\overline{\phi_{0,t}}(Z) = \sum_{n,l \in \mathbb{Z}} g(n, l) \exp(2\pi i \text{tr}(NZ)).$$

where $N = \left( \begin{array}{c} n \\ l/2 \\ t \end{array} \right) \in M_2(\mathbb{Z})$ (t is fixed). In accordance with (3.5) we get

$$\overline{\phi_{0,t}}|T_0(p)(Z) =$$

$$\sum_{M \in \Gamma_{\infty} \setminus T_0(p)} \overline{\phi_{0,t}}(M_i(Z)) = p^3 \sum_{l \equiv 0 \mod p} \sum_{n,l \in \mathbb{Z}} g\left(\left( \begin{array}{c} n \\ l/2 \\ t \end{array} \right) \right) \exp\left(2\pi i \text{tr}(p^{-2}N\left[ \begin{array}{c} 1 \\ 0 \\ p \end{array} \right]Z)\right)$$

$$+ \sum_{n,l \in \mathbb{Z}} G_p(N) g(N) \exp(2\pi i \text{tr}(NZ)) + \sum_{n,l \in \mathbb{Z}} g(N) \sum_{\lambda \mod p} \exp(2\pi i \text{tr}(N\left[ \begin{array}{c} 0 \\ \lambda \end{array} \right]Z))$$

where $N[M] = \left(t^t M N M\right)$ and we denote by $G_p(N)$ the Gauss sum

$$G_p(n, l, t) = -p + \sum_{a,b \mod p} \exp\left(2\pi i \frac{na + lab + t^2}{p}\right).$$

Changing $N$ to $N[M^{-1}]$ in the first and third sum, we get the formula for the Fourier coefficient $g_p(n, l)$ of Jacobi form $\phi_{0,t}|T_0(p)(\tau, z)$ of index $t$

$$g_p(n, l) = p^3 g(p^2 n, pl) + G_p(n, l, t) g(n, l) + \sum_{\lambda \mod p} g\left(\frac{n + \lambda l + \lambda^2 t}{p^2}, \frac{l + 2\lambda t}{p}\right)$$

(3.6)

where we put $g(n, l) = 0$ if $n \not\equiv Z$ or $l \not\equiv Z$. In the case of a good reduction, when $(p, t) = 1$, the $G_p(N)$ is given by the formula

$$G_p(n, l, t) = p\left(\frac{-4nt - l^2}{p}\right), \quad (p, t) = 1.$$  

If $p|t$, we can represent the formula for $G_p$ in the form useful for exact calculations

$$G_p(n, l, t) = p\begin{cases} 0 & \text{if } l \not\equiv 0 \mod p \\ p-1 & \text{if } (n, l) \equiv (0, 0) \mod p \\ -1 & \text{if } n \not\equiv 0 \mod p, \text{ and } l \equiv 0 \mod p. \end{cases}$$

For the Fourier coefficients depending on $\lambda$ in (3.6) we have $\det(N\left[ \begin{array}{c} 0 \\ \lambda \end{array} \right]) = p^2 \det(N)$. If $(t, p) = 1$, then $n + \lambda l + \lambda^2 t$ is a full square mod $p$ for $4nt - l^2 \equiv 0 \mod p^2$. Thus there exists only one $\lambda \mod t$ which gives us a non-trivial term in the third summand in (3.6). Therefore we prove
Lemma. Let us suppose that the Fourier coefficient \(g(n, l)\) of the Jacobi form \(\phi_{0,1}\) of weight zero and index \(t\) depends only on the norm \(N = 4nt - l^2 \in \mathbb{Z}\). We denote \(g(N) = g(n, l)\). For any prime \(p\) such that \((t, p) = 1\), the Fourier coefficients of \(\phi_{0,1}(T_0(p))\) are given by the formula

\[
g_p(N) = p^3 g(p^2 N) + p \left( \frac{-N}{p} \right) g(N) + g(\frac{N}{p^2})
\]

where we set \(g(\frac{N}{p^2}) = 0\) if \(\frac{N}{p^2} \notin \mathbb{Z}\).

The Igusa modular form \(\Delta_{35}(Z)\). The Igusa modular form \(\Delta_{35}(Z)\) is the first Siegel modular form of odd weight with respect to \(\Gamma_1 = Sp_4(\mathbb{Z})\). It has weight 35 (see [IG1]). We defined this modular form in [GN4] as a Hecke product of \(\Delta_5(Z)\).

Let us take the modular form \(\Delta_5(Z)\) which has the divisor \(H_1\) in \(A_1\). Using the system of representatives \(T(p)\), we then get

\[
[\Delta_5(Z)]_{T(2)} = \prod_{a,b,c \mod 2} \Delta_5(\frac{s_1+a}{2}, \frac{s_2+b}{2}, \frac{s_3+c}{2}) \prod_{a \mod 2} \Delta_5(\frac{s_1+a}{2}, z_2, 2z_3) \Delta_5(2z_1, z_2, \frac{s_1+a}{2}) \\
\times \Delta_5(2z_1, 2z_2, 2z_3) \prod_{b \mod 2} \Delta_5(2z_1, -z_1 + z_2, \frac{s_1-2z_2+z_3+b}{2}).
\]

One can check that \(\text{div}_{A_1}([\Delta_5(Z)]_{T(p)}) = (p+1)^2 H_1 + H_{p^2}\). Thus

\[
\Delta_{35}(Z) = \frac{[\Delta_5(Z)]_{T(2)}}{\Delta_5(Z)^8} = \text{Exp-Lift}(\phi_{0,1}((T_0(2) - 2)) \in \mathfrak{M}_{35}(\Gamma_1)
\]

and

\[
\Delta_{35}(Z) = q^2 r s^2 (q - s) \prod_{n,l,m \in \mathbb{Z}} (1 - q^n r s^m) f_1^{(2)}(4nm-l^2)
\]

where \(f_1(4n - l^2) = f_1(n, l)\) are the Fourier coefficients of \(\phi_{0,1}(r, z)\) (see (2.4)) and

\[
f_1^{(2)}(N) = 8 f_1(4N) + 2 \left( \frac{-N}{2} \right) - 1) f_1(N) + f_1(\frac{N}{4})
\]

according to Lemma above. Remark that we cannot construct \(\Delta_{35}(Z)\) as an arithmetic lifting of a holomorphic Jacobi form. Nevertheless we get \(\Delta_{35}(Z)\) as a finite Hecke product of the lifted form \(\Delta_5(Z)\). In particular, from the infinite product formula follows the formula for the second Fourier-Jacobi coefficient \(\phi_{35,2}\) of the Igusa modular form

\[
\phi_{35,2}(r, z) = \eta^{60}(r) \theta_{11}(r, 2z) = -q^2 r^{-1} \prod_{n \geq 1} (1 - q^{n-1} r^2)(1 - q^n r^{-2})(1 - q^n)^70.
\]

(Remark that \(\phi_{35,1} = 0\).)
The modular form $D_6(Z)$. Using (3.2)-(3.3) and Lemma above we get modular forms with divisor $H_p$ in $A_2^+$ and $A_3^+$ respectively

$$F_p^{(2)}(Z) = c_2 \left[ \frac{\Delta_2(Z)}{(p+1)^2} \right]_{T(p)} = \text{Exp-Lift} \left( \phi_{0,2} \right) \in \mathfrak{M}_{2p} \left( \Gamma_2 \right),$$

$$F_p^{(3)}(Z) = c_3 \left[ \frac{\Delta_1(Z)}{(p+1)^2} \right]_{T(p)} = \text{Exp-Lift} \left( \phi_{0,3} \right) \in \mathfrak{M}_{p} \left( \Gamma_3, \chi_3^{(p)} \right)$$

where $p \neq 2$ for $\Delta_2$ and $p \neq 3$ for $\Delta_1$. The character $\chi_2^{(p)}$ is trivial or has order two.

(The $c_p$ are constants which can be easily calculated.) In particular we get the modular form

$$D_6(Z) = \frac{2^{22} \left[ \Delta_1(Z) \right]_{T(2)} \Delta_2(Z)}{\Delta_1(Z)^8} = \text{Exp-Lift} \left( \phi_{0,3} \right) \left( T_0(2) - 3 \right).$$

Thus according to (3.9) where

$$\phi_{0,3}(\tau, z) = \phi_{0,3}(T_0(2) - 3)(\tau, z) = \sum_{n,l} g_3(n, l) q^n r^l = r^2 - r + 12 - r^{-1} + r^{-2} + q(\ldots).$$

Example. Hecke product for $p = t = 2$ and $p = t = 3$. Using (3.6) we can consider the cases of bad reduction $p = t = 3$ and $p = t = 3$. The Hecke operator $T^+(2) = \Gamma_2^+ \text{ diag}(1, 1, 2, 2) \Gamma_2^+$ from the Hecke ring $H(\Gamma_2^+)$ of the maximal normal extension $\Gamma_2^+$ contains 18 left cosets: the 15 cosets from (3.3) and

$$\sum_{a, b \mod 2 \neq (0, 0)} \Gamma_2^+ \left( \begin{array}{ccc} -a & 2 & b \\ 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 2 \\ a \end{array} \right).$$

Therefore the modular form $[\Delta_2]_{T^+(2)}$ of weight 36 has divisor $2H_4 + 9H_1$ and we obtain the identity

$$\Delta_{11}(Z)^2 = \left( \text{Lift}(\eta^{21}(\tau) \vartheta(2, Z)) \right)^2 = \left( \text{Exp-Lift}(\phi_{0,2}^{(11)}) \right)^2$$

$$= c \left[ \Delta_2 \right]_{T^+(2)} / \Delta_2(Z) = \text{Exp-Lift} \left( \phi_{0,2} | T_0(2) \right)(Z)$$

where

$$\phi_{0,2}^{(11)} = \phi_{0,1} | T_-(2) - 2\phi_{0,2} = \phi_{0,1}^2 - 20\phi_{0,2} = \frac{1}{2} \phi_{0,2} | T_0(2). \quad (3.7)$$

because

$$\phi_{0,2} | T_0(2) = 2r^2 + 44 + 2r^{-2} + q(\ldots).$$

The identity (3.7) gives us relations between the "fundamental" Jacobi forms $\phi_{0,1}$ and $\phi_{0,2}$.

Similarly to the case $p = 2$ we obtain for $p = t = 3$ the Jacobi form $\phi_{0,3} | T_0(3)(\tau, z) = 2r^3 + 68 + 2r^{-3} + q(\ldots)$. Therefore the Hecke product for $p = 3$ of $\Gamma_3$-modular form $\Delta_1$ is related with

$$F_{16}^{(3)}(Z) = \text{Exp-Lift} \left( \frac{1}{2} \phi_{0,3} | (T_0(3) - 2) \right) \in \mathfrak{M}_{16}(\Gamma_3, \nu_0^8 \times \text{id}_H)$$
with divisor $H_9$. One can construct this modular form using multiplicative 3-symmetrisation of $\Delta_5$. In terms of Jacobi forms it is equivalent to the relation

$$\phi_{0,3}|T_0(3) = 2\phi_{0,1}|T_- (3) - 6\phi_{0,3}.$$  

Recall that the Jacobi form $\phi_{0,3}(\tau, z)$ is the square of an infinite product (see (2.8)).

**Example.** $\Gamma_4$-modular forms with $H_{p^2}$-divisors. Our next examples are connected with the Jacobi form $\phi_{0,4}$ (see (2.6)). In the case of good reduction ($p \neq 2$), we can define the same function as above. Since

$$\phi_{0,4}|T_0(p)(\tau, z) = r^p + pr + (p^3 + 1) + r^{-p} + pr^{-1} + q(\ldots) \quad (p \neq 2)$$

we obtain a modular form

$$F_{p}^{(4)}(Z) = \text{Exp-Lift}(\phi_{0,4}|(T_0(p) - p - 1)) \in \mathfrak{M}_{p(p^2 - 1)/2}(\Gamma_4, \tau^{p^2 - 1}) \times \text{id}_H$$

with divisor $H_{p^2}$. For instance for $p = 3$ we get a modular form of weight 12 with divisor $H_9$ in $A_4^+$. Using (3.6) for $p = 2$, we obtain a very nice identity

$$\phi_{0,4}|T_0(2)(\tau, z) = \phi_{0,1}(\tau, 2z).$$  (3.8)

It gives us the second new formula for the generator $\phi_{0,1}(\tau, z)$ (see [2.7]). We can represent it in an equivalent form using the operator $\Lambda_2^*$ dual to $\Lambda_2^*$. One can check (see [G2]) that

$$p^{-1}T_0(p) \cdot \Lambda_2^* = T_+(1, p^2) = \sum_{a,b,c \mod p^2} \Gamma_{\infty} \left( \begin{array}{ccc} 1 & a & pb \\ 0 & b & c \\ 0 & 0 & 0 \end{array} \right) + \sum_{a,b \mod p} \Gamma_{\infty} \left( \begin{array}{ccc} p & 0 & a \\ 0 & 1 & b \\ 0 & 0 & c \end{array} \right)$$

$$+ \sum_{a \mod p} \Gamma_{\infty} \left( \begin{array}{ccc} p^2 & 0 & 0 \\ -a & 0 & c \\ 0 & 0 & p \end{array} \right).$$

Thus (3.8) is equivalent to

$$8\phi_{0,1}(\tau, z) = \phi_{0,4}|T_+(1, 4)(\tau, z).$$  (3.9)

We recall that $\phi_{0,4}(\tau, z)$ is given by an infinite product (see (2.6)). One can find a formula for the action of $T_+(1, 4)$ on Fourier coefficients of Jacobi forms similar to the formula (3.19) for $T_+(2)$.

**Anti-symmetric Modular Forms.**

The arithmetic lifting provides us with modular forms which are invariant with respect to the main exterior involution $V_t$ of the group $\Gamma_t$ (see the beginning of §2). Using the exponential lifting, one can construct anti-invariant modular forms, i.e. forms satisfying $F(V_t(Z)) = -F(Z)$. For example for $t = 1$ the Igusa modular form $\Delta_{35}(Z)$ is anti-invariant.
Existence Theorem. (see [GN6]) For arbitrary $t > 1$ there exists an anti-symmetric modular form of weight 12 with respect to $\Gamma_t$ with trivial character.

We construct below such forms for $t = 2, 3, 4$ and show that for these $t$ anti-symmetric form of weight 12 is unique.

Let us consider the function $\psi_{0, t}(\tau, z) = \Delta(\tau)^{-1}E_{12, t}(\mathcal{T}, z)$ where

$$\Delta(\tau) = \sum_{n \geq 0, \iota} \frac{q^n}{\iota}$$
and $E_{12, t}(\tau, z)$ is a Jacobi-Eisenstein series of weight 12 and index $t$.

There exists a formula for Fourier coefficients of $E_{2, 1}$ in terms of H. Cohen’s numbers (see [EZ, §2]). One can find the table of the values of Fourier coefficients of $E_{4, 1}(\tau, z)$ and $E_{6, 1}(\tau, z)$ in [EZ, §1]. Using the basic Jacobi forms $\phi_{0, 2}(\tau, z) = r^{\pm 1} + 4 + \ldots$, $\phi_{0, 3}(\tau, z) = r^{\pm 1} + 2 + \ldots$ and the forms $\phi_{0, 2}(11) = r^{\pm 2} + 22 + \ldots$ and $\phi_{0, 3}(6) = r^{\pm 2} - r^{\pm 1} + 12 + \ldots$, which are the data for the exponential liftings in §2. We define

$$\psi_{0, 2}(\tau, z) = \Delta(\tau)^{-1}E_{6, 1}(\tau, z)^2 - 2\phi_{0, 2}(11)(\tau, z) + 176\phi_{0, 2}(\tau, z)$$
$$= \sum_{n \geq 0, \iota} c_2(n, l)q^n r^l = q^{-1} + 24 + q(\ldots),$$
$$\psi_{0, 3}(\tau, z) = \Delta(\tau)^{-1}E_{4, 1}(\tau, z)^3 - 3\phi_{0, 3}(6)(\tau, z) - 171\phi_{0, 3}(\tau, z)$$
$$= \sum_{n \geq 0, \iota} c_3(n, l)q^n r^l = q^{-1} + 24 + q(\ldots).$$

The Jacobi forms $\psi_{0, p}$ ($p = 2, 3$) contain the only type of Fourier coefficients with indices of negative norm. This is $q^{-1}$ of norm $-4p$. Thus we can use both functions to produce the exponential liftings

$$\Psi_{12}^{(2)}(Z) = \text{Exp-Lift}(\psi_{0, 2}) = q \prod_{n, l, m \in \mathbb{Z}} (1 - q^n r^l s^{2m}) c_2(n, l, m) \in \mathfrak{M}_{12}(\Gamma_2),$$
(3.10)
$$\Psi_{12}^{(3)}(Z) = \text{Exp-Lift}(\psi_{0, 3}) = q \prod_{n, l, m \in \mathbb{Z}} (1 - q^n r^l s^{2m}) c_3(n, l, m) \in \mathfrak{M}_{12}(\Gamma_3).$$
(3.11)

According to Exponential Lifting Theorem

$$\Psi_{12}^{(p)}(V_p < Z >) = -\Psi_{12}^{(p)}(Z) \quad (p = 2, 3) \quad \text{and} \quad \text{Div}_{A_p}(\Psi_{12}^{(p)}) = \begin{cases} H_8 & \text{for } p = 2 \\ H_{12} & \text{for } p = 3. \end{cases}$$

The Fourier-Jacobi expansion of $\Psi_{12}^{(p)}$ starts with coefficients

$$\Psi_{12}^{(p)}(Z) = \Delta_{12}(\tau) - \Delta_{12}(\tau) \psi_{0, p}(\tau, z) \exp(2\pi i \rho \omega) + \ldots.$$

Therefore the constructed modular forms $\Psi_{12}^{(p)}(Z)$ ($p = 2, 3$) are not cusp forms.
If we do the same for $t = 4$, we get a Jacobi form we used to construct $\Delta_{35}(Z)$. Let us take the Jacobi form

$$\phi_{0,1}((T_0(2) - 2)(\tau, 2z) = q^{-1} + (r^4 + 70 + r^{-4}) + q(\ldots).$$

Its exponential lifting is zero along two Humbert surfaces with discriminant 16. To delete the second component, we consider the additional Jacobi–Eisenstein series which has the constant term equals zero (such a series exists if the index contains a perfect square). For $t = 4$ this Jacobi–Eisenstein series is the eight power of the Jacobi theta-series $\theta(\tau, z)$.

Using $\theta(\tau, z)^8$, we define

$$\psi_{0,4}(\tau, z) = (\phi_{0,1}((T_0(2) + 26)(\tau, 2z) - \Delta(\tau)^{-1}E_2(\tau, z)^8 - 8(\phi_{0,4}((T_0(3) + 4))(\tau, z)$$

$$= \sum_{n \geq 0, l \in \mathbb{Z}} c_4(n, l)q^n r^l = q^{-1} + 24 + q(\ldots).$$

Similarly to $\psi_{0,2}$ and $\psi_{0,3}$ the Jacobi form $\psi_{0,4}$ contains only the Fourier coefficients of type $q^{-1}$ with index of negative norm. Taking its exponential lifting we obtain the $\Gamma_4$-modular form of weight 12

$$\Psi_{12}^{(4)}(Z) = \text{Exp-Lift}(\psi_{0,4})(Z) = q \prod_{n, l, m \in \mathbb{Z}} (1 - q^{n} r^{l} s^{4m})c_4(nm, l) \in \mathfrak{M}_{12}(\Gamma_4). \quad (3.12)$$

The modular form $\Psi_{12}^{(4)}(Z)$ is anti-invariant and $\text{Div}_{A_4}(\Psi_{12}^{(4)}) = H_8(0)$.

Uniqueness of $\Psi_{12}^{(t)}$ for $t = 2, 3, 4$. Arbitrary anti-invariant modular form is automatically zero along the Humbert surface $H_{4t}(0) = \pi_t\{\tau - tw = 0\}$. The modular forms constructed above have this surfaces as full divisor. Thus they are unique.

Remark. After this conference a preprint of Ibukiyama and Onodera [OK] has been appeared where an anti-invariant modular form of weight 12 with respect to $\Gamma_2$ was constructed in terms of Siegel theta-constants.
