Kyoto University
1. Introduction.
Let \( D \) be a bounded domain in \( \mathbb{R}^d \) with \( C^2 \)-boundary \( \partial D \). \( K \) denotes a closed subset of \( \partial D \). The uniformly elliptic operator \( L \) is defined by

\[
L = \frac{1}{2} \sum_{i,j=1}^{d} a_{i,j}(x) \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{d} b_i(x) \frac{\partial}{\partial x_i}
\]

where the coefficients \( A = (a_{i,j}), b = (b_i) \) are all bounded continuous functions on \( D \). More precisely, the Hölder continuity with exponent \( \lambda \) is assumed, namely, \( a_{i,j}, b_i \in C^{0,\lambda}(D) \) for every \( i,j \). We assume, in addition

(A.1) \( a_{i,j} \in C^2(D), \ b_i \in C^1(D) \); (A.2) \( \sum_{i,j=1}^{d} \frac{\partial^2}{\partial x_i \partial x_j} a_{i,j}(x) \leq \sum_{i=1}^{d} \frac{\partial}{\partial x_i} b_i(x) \).

Our main concern is the problem on the removable singularity for nonlinear differential equations. We consider the boundary value problem for nonlinear elliptic equations:

\[
Lu = u^\alpha \text{ in } D \ (\alpha > 1), \text{ with } u|_{\partial D \setminus K} = f. \tag{1}
\]

We would like to know when the restriction \( \partial D \setminus K \) of the solution \( u \) is replaced by the whole boundary \( \partial D \). Then if that is possible, \( K \) is called the removable boundary singularity (RBS). It is a not only interesting but also important problem to think about what kind of characterization for removability of the singularity \( K \) is possible. Another interesting problem is on the explosive solution at the boundary. Consider the following problem:

\[
Lu = u^\alpha \text{ in } D \text{ with } u|_{\partial D} = \infty. \tag{2}
\]

*Research supported in part by JMESC Grant-in-Aid SR(C) 07640280 and also by JMESC Grant-in-Aid CR(A)(1) 09304022, CR(A)(1) 10304006.
The second expression in the above means that $\lim_{D \ni y \to x} u(y) = \infty$ for $\forall x \in \partial D$. We are interested in describing the probabilistic characterization of the solution with explosion at the boundary. These two problems are mutually related, however, we shall treat the former problem only and leave the latter one for our next paper. For a function space $F$, $pbF$ indicates the subspace of $F$ whose elements are all positive bounded functions.

The Hausdorff measure of $A (\subset \mathbb{R}^d)$ with parameter $s$ is given as follows. For $\varepsilon > 0$, $\Delta(\varepsilon)$ is a countable open covering $(N(\varepsilon), \{B(x_i, r_i)\}_i)$ of $A$ such that $A \subset \bigcup_{i=1}^{N(\varepsilon)} B(x_i, r_i)$ where $B(x_i, r_i)$ is an open ball with center $x_i$ and radius $r_i$, $0 < r_i \leq \varepsilon$. Then the Hausdorff measure $\Lambda^s(A)$ of $A$ is defined by

$$\Lambda^s(A) = \lim_{\varepsilon \downarrow 0} \left( \inf_{\Delta} \sum_{1=}^{N(\varepsilon)} r_i^s \right).$$

The Hausdorff dimension $\dim_H(A)$ of $A$ is the supremum of $s \in \mathbb{R}_+$ such that $\Lambda^s(A) > 0$. The interpretation of the problem (1) as classical problem means that the nonnegative solution $u$ lying in $C^2(D)$ satisfies

$$Lu = u^\alpha \text{ in } D, \lim_{D \ni x \to y} u(x) = f(y), \forall y \in \partial D \setminus K, \quad (3)$$

for $f \in pC(\partial D)$. The first assertion is a result on nonremovable singularity.

**Theorem 1.** For some positive number $\gamma(\alpha)$, $\alpha > 1$ satisfying that $\gamma$ is monotone decreasing in $\alpha$ and $\gamma / \gamma \to \infty$ as $\alpha \searrow 1$, there exists a family of solutions $\{u \equiv u_\alpha \geq 0; \alpha > 1\}$ of the boundary value problem (3) such that $d > \gamma(\alpha)$ and $\Lambda^s(K) > 0$ for some $s \in (d - \gamma(\alpha), d - 1], (\alpha > 1)$.

Let $dx$ be the Lebesgue measure on $\mathbb{R}^d$, and $n$ denotes the unit exterior normal vector to the boundary $\partial D$. $S(dy)$ is the surface measure on $\partial D$. We set $\mu(dx) = p(x)dx$, where $p(x)$ is the distance function from $x$ to the boundary $\partial D$. Under the assumptions (A.1) and (A.2), the operator $L$ has an expression of the divergence form

$$Lu = \sum_{i,j=1}^{d} \frac{\partial}{\partial x_j} \left( a_{ij}(x) \frac{\partial}{\partial x_i} u \right) - \frac{\partial}{\partial x_i} (\hat{b}_i(x)u) - c(x)u$$

with $\hat{b}_i = -b_i + \sum_j \partial_j a_{ij}$, $c = -\sum_i \partial_i \hat{b}_i$, $\partial_i = \partial/\partial x_i$, $(i = 1, 2, \ldots, d)$. Then notice that $a_{ij}, \hat{b}_i \in C^1(D)$ and $c \geq 0$. The adjoint of $L$ is given by

$$L^* u = \sum_{i,j} \partial_i(a_{ij} \partial_j u) + \sum_i \hat{b}_i \partial_i u - cu.$$  

Now we shall introduce another interpretation of (1), due to the Gmira-Véron formulation (1991). That is, the solution is a nonnegative function $u \in C^2(D) \cup C(D \setminus K)$ satisfying

$$\int_D \{ -u \cdot L^* g + u^\alpha g \} dx + \int_{\partial D} f \frac{\partial g}{\partial n} S(dy) = 0 \quad (4)$$
for $\forall g \in C^{1,1} \left( \overline{D} \right) \cap W_{0}^{1,\infty}(D)$ with the compact support which is contained in $\overline{D} \setminus K$.

**Theorem 2.** Let $u$ be a solution of (4). If $\dim_{H}(K) < d - \gamma(\alpha)$ and

$$u \in L^{\frac{1}{\gamma(\alpha)-1}+1}(dx) \bigcap L^{\alpha}(\mu(dx)), $$

then $K$ is the RBS.

N.B. The above-mentioned result is an extension of Sheu’s theorem (1994) (cf. Theorem 2, p.702, [Sh94]).

2. **Probabilistic Characterization.**

Next we shall discuss the equivalence problem to the RBS. Let $\xi = (\xi_{t}, \Pi_{x})$ be the $L$-diffusion process. $\tau = \inf \{ t > 0; \xi_{t} \notin D \}$ is the first exit time of the process $\xi$ from the domain $D$. A boundary element $x \in \partial D$ is called a regular point if $\Pi_{x}(\tau = 0) = 1$ holds for the first exit time $\tau$. When we say that the domain $D$ is regular, we mean that $D$ has a regular boundary. $M_{F}(R^{d})$ denotes the totality of finite measures on $R^{d}$. $(\mu, f)$ indicates the integral of $f$ with respect to the measure $d\mu$. Let $X = (\Omega, F, P_{m}, X_{t}, F_{t})$ be a finite measure valued branching Markov process associated with the equation $L = Lu - u^{\alpha} = 0$ in the sense of Dynkin (1994). Alternatively, for each $m \in M_{F}(R^{d})$, there exists a probability measure $P_{m}$ on $(\Omega, F)$ such that $X_{0} = m$, $P_{m}$-a.s., and for $\varphi \in \text{Dom}(L)$

$$M_{t}(\varphi) := \langle X_{t}, \varphi \rangle - \langle X_{0}, \varphi \rangle - \int_{0}^{t} \langle X_{s}, L\varphi \rangle ds, \quad \forall t \geq 0 $$

is a continuous $(F_{t})$-martingale under $P_{m}$, and the quadratic variation is given by

$$\langle M_{.}(\varphi) \rangle_{t} = \int_{0}^{t} \langle X_{s}, \varphi^{2} \rangle ds, \quad \forall t \geq 0, \quad P_{m} - \text{a.s.} $$

The support $\text{supp}X_{t}$ of a random measure $X_{t}$ for each $t > 0$ is the minimal closure of closed sets $G \subset R^{d}$ such that $X_{t}(G^{c}) = 0$ holds. The range of $X$ is defined by

$$\mathcal{R}(X) := \bigcup_{t \geq 0} \left( \bigcup_{\varepsilon > 0} \text{closure of } \text{supp}X_{t} \right) \bigcap \left( \bigcup_{t \geq \varepsilon} \text{supp}X_{t} \right).$$

Note that $\mathcal{R}(X)$ is a random set. We say that a set $F$ is $\mathcal{R}$-polar if $P_{x}(\mathcal{R}(X) \cap F = \emptyset) = 0$ holds for $\forall x \notin F$. Similarly we may define the concept of boundary polar set. We say that a set $K$ is $\partial$-polar if $P_{x}(\mathcal{R}(\tilde{X}_{D}) \cap K = \emptyset) = 0$ holds for $\forall x \notin K$, where $\tilde{X}_{D}$ is a part of $X$ in the domain $D$.

**Theorem 3.** Let $D$ be a bounded regular domain in $R^{d}$. Then $K$ is the RBS if and only if $K$ is $\partial$-polar.

3. **Sketch of Proofs.**
As to the proof of Theorem 1, assume first of all that $\Lambda^{s}(K) > 0$. Take a measure $\pi \in M_{F}(K)$ such that $\pi(B) \leq r^{s}$, for any ball $B$ in $\mathbb{R}^{d}$ with radius $r$. For the Poisson kernel $k_{L}(x, y)$ for the elliptic operator $L$ ([DK96]), the function
\[ \hat{K}(x) := \int_{K} k_{L}(x, y) \pi(dy) \]
is $L$-harmonic in $D$ and vanishes on $\partial D \setminus K$. We show that $\hat{K} \in L^{\alpha}(\mu(dx))$. By virtue of Maz’ya-Plamenevsky’s argument (1985), it follows from Maz’ya’s lemma (1975) that there exists a constant $C > 0$ (depending on $L$ and $D$) such that $k_{L}(x, y) < C \cdot p(x) |x - y|^{-d}$ holds for all $x \in D$, $y \in \partial D$. By this estimate, it is sufficient to show that
\[ l(x) := \int_{D} \left( p(x)/|x - y|^{d} \right) \pi(dy) \in L^{\alpha}(\mu(dx)). \tag{5} \]

To show (5) can be attributed to finding a constant $C$ such that
\[ \int_{D} l(x) g(x) \mu(dx) \leq C \quad \text{for any } g > 0 \tag{6} \]
satisfying that $\int_{D} \{ g(x) \}^{\beta} \mu(dx) = 1$ with $1/\alpha + 1/\beta = 1$. Consider the function
\[ F(z) = \int_{D} \int_{K} \frac{\{ g(x) \}^{\beta} p(x)}{|x - y|^{s/\alpha + (d - \gamma(\alpha))/\beta + (d - s + 1)z + 1}} \pi(dy) \mu(dx). \]

It is easy to verify that $|F(1 + ib)| < \infty$. Thus we attain (6). On this account, the conclusion yields from a routine work with the maximum principle and a discussion of domination of the maximal solution by some $L$-harmonic function.

The proof of Theorem 2 is greatly due to a variant of Chabrowski’s lemma (1991). Put $\beta = d - \gamma(\alpha)$. $K$ is a closed set in $\partial D$ such that $\Lambda^{\beta}(K) = 0$. Consequently, for $\varepsilon > 0$ there can be found a covering $\{ G_{n}^{[\varepsilon]}; n = 1, \ldots, N(\varepsilon) \}$ of $K$ such that (i) $G_{n}^{[\varepsilon]}$ is a $d$-dimensional closed cube with edge of length $a_{n} = 2^{-k_{n}} < \varepsilon$, $k_{n} \in \mathbb{Z}^{+}$, and $a_{1} \geq a_{2} \geq \cdots \geq a_{N(\varepsilon)}$; (ii) $(G_{n}^{[\varepsilon]})^{n} \cap (G_{m}^{[\varepsilon]})^{n} = \emptyset$ if $n \neq m$; (iii) $\sum_{n=1}^{N(\varepsilon)} a_{n}^{\beta} \leq 1$. This $\{ G_{n}^{[\varepsilon]} \}$ is called the standard covering of $K$ corresponding to $\varepsilon$ if
\[ \sum_{n=1}^{N(\varepsilon)} a_{n}^{d - \gamma(\alpha)} \to 0 \]
as $\varepsilon \searrow 0$.

**Lemma 4.** Let $\{ G_{n}^{[\varepsilon]} \}$ be the standard covering of $K$ corresponding to some $\varepsilon > 0$. Then there exists a family of functions $\{ g_{n} \}_{n}$ such that
(a) $g_{n} \in pC_{0}^{\infty}(\mathbb{R}^{d})$, $\text{supp} g_{n} \subset 2G_{n}$ for $\forall n$.
(b) $0 \leq \sum_{n=1}^{N(\varepsilon)} g_{n}(x) \leq 1$ for $\forall x \in \mathbb{R}^{d}$.
(c) $\sum_{n} g_{n}(x) = 1$ for $\forall x \in \bigcup_{n=1}^{N(\varepsilon)} (3/2)G_{n}^{[\varepsilon]}$
(d) there exists a constant $c = c(d) > 0$ such that for $x \in \mathbb{R}^{d}$, $n = 1, \ldots, N(\varepsilon)$
\[ \left| \frac{\partial}{\partial x_{i}} \sum_{j=1}^{n} g_{j}(x) \right| \leq \frac{c}{a_{n}}, \quad \left| \frac{\partial^{2}}{\partial x_{i} \partial x_{k}} \sum_{j=1}^{n} g_{j}(x) \right| \leq \frac{c}{a_{n}^{2}}, \quad (i, k = 1, \ldots, d). \]
For an arbitrary $\epsilon > 0$, choose $\{g_n\}_n$ as in Lemma 4. Put $k_p(x) = \sum_{j=1}^p g_j(x)$, and $h_p(x) = 1 - k_p(x)$ for any $x \in \mathbb{R}^d$, $(0 \leq p \leq N \equiv N(\epsilon))$. Take $g \in C^{1,1}(\overline{D}) \cap W_{0}^{1,\infty}(D)$ with compact support in $\overline{D}$. Since $g \cdot h_N \in C^{1,1}(\overline{D}) \cap W_{0}^{1,\infty}(D)$ with supp$(g \cdot h_N)$ (which is contained in $\overline{D} \setminus K$), by (4) we obtain

$$\int_D \{-u \cdot L^*(gh_N)\}dX + \int_D u^\alpha \cdot gh_NdX = -\int_{\partial D} f \cdot \frac{\partial(gh_N)}{\partial n}S(dy). \tag{7}$$

Clearly it follows that

$$\lim_{\epsilon \to 0} \int_D u^\alpha \cdot gh_NdX = \int_D u^\alpha \cdot gdx, \tag{8}$$

$$\lim_{\epsilon \to 0} \int_{\partial D} f \frac{\partial(gh_N)}{\partial n}dS = \int_{\partial D} f \frac{\partial g}{\partial n}dS. \tag{9}$$

Since $L^*(gh_N) = \sum_{i,j} \partial_i(\partial_j(gh_N)) + \sum_i \hat{b}_i \partial_i gh_N - c(gh_N)$ with $\hat{b}_i = -b_i + \sum_j \partial_j a_{ij}$ and $c = -\sum_i \partial_i \hat{b}_i$, we have

$$I_1 := \int_D u \cdot \sum_{i,j} \partial_i (a_{ij} \cdot \partial_j gh_N) dx$$

$$= \int_D u \sum_{ij} (\partial_i a_{ij})(\partial_j gh_N)dx + \int_D u \sum_{ij} a_{ij} (\partial_i^2 gh_N)dx \equiv I_{11} + I_{12}.$$  

As to $I_{11}$ it suffices to estimate the integral of the summation of those terms like $(\partial_i a_{ij})(\partial_j gh_N)$, $(\partial_i a_{ij})g \cdot (\partial_j h_N)$. Likewise, as to $I_{12}$ we need to consider the sum of the terms $\partial_i g \cdot h_N, \partial_g \cdot h_N, \partial g \cdot \partial_j h_N,$ and $g \cdot \partial_i^2 h_N$. Set

$$I_2 := \int_D u \sum_i \hat{b}_i (\partial_i gh_N) dx = -\int_D u \sum_i b_i \cdot \partial_i gh_N dx + \int_D u \sum_{ij} (\partial_i a_{ij}) \cdot \partial_i gh_N dx.$$  

As for $I_2$, we have to take care of the terms $\partial_i g \cdot h_N + g \cdot \partial_i h_N$ multiplied by $b_i$ or by $\partial_j a_{ij}$. Moreover, we put

$$I_3 := \int_D c gh_N dx = \int_D \sum_i \partial_i b_i \cdot [gh_N]dx - \int_D \sum_{ij} (\partial_i^2 a_{ij}) \cdot [gh_N]dx.$$  

Because it is rather longsome to discuss all of the above integral terms, we shall mention below only two of them. Those calculations explain almost everything important and essential involved with the others. For instance, let us consider the integral $I_{12*} = \int u \cdot \sum_{i,j} a_{ij} \partial_i g \cdot \partial_j h_N dx$. Since

$$\text{supp} \left( \sum_{j=1}^{N(\epsilon)} g_j(x) \right) \subset \bigcup_{j=1}^{N(\epsilon)} 2G_j^{[\epsilon]},$$

from the condition (a) of Lemma 4, we have supp$(h_N(x)) \subset \bigcup_{j=1}^{N} 2G_j^{[\epsilon]}$. By the assumptions on the coefficients $A = (a_{ij})$, we can find some constant $C > 0$ and $I_{12*}$ is able to be estimated majorantly by

$$C \int_{D \cap \bigcup_{j=1}^{N} 2G_j^{[\epsilon]}} u \cdot \sum_{i=1}^d \left| \frac{\partial h_N}{\partial x_i} \right| dx. \tag{10}$$
because \( g \in C^{1,1}(\bar{D}) \). For simplicity, set \( D(G_{*},N,\varepsilon) := D \cap (\bigcup_{j=1}^{N} 2G_{j}^{[\varepsilon]}), \) and

\[
A := \int_{D(G_{*},N,\varepsilon)} u^{1+\frac{\alpha}{d}-1} dx, \quad B := \int_{D(G_{*},N,\varepsilon)} \left( \sum_{i=1}^{d} \left| \frac{\partial h_{N}}{\partial x_{i}} \right| \right)^{\gamma(\alpha)} dx.
\]

An application of the Hölder inequality to (10) reads Eq. (10) \( \leq C \cdot A^{1-1/\gamma(\alpha)}, B^{1/\gamma(\alpha)}. \) Note that \( A \to 0 \) as \( \varepsilon \to 0 \) since \( u \in L^{1+1/(\gamma(\alpha)-1)}(dx) \) and the Lebesgue measure of \( \bigcup_{i} 2G_{i}^{[\varepsilon]} \) vanishes as \( \varepsilon \to 0. \) So that, if \( B \) is bounded, then we know that \( I_{1,2*} \) becomes null as \( \varepsilon \) goes to zero. The boundedness of \( B \) yields from the following estimate. Put

\[
U_{N} := 2G_{N}^{[\varepsilon]}, \quad \text{and} \quad U_{p} := 2G_{p}^{[\varepsilon]} - \bigcup_{i=p+1}^{N} 2G_{i}^{[\varepsilon]}, \quad (1 \leq p \leq N - 1).
\]

Notice that \( h_{N} = h_{p} \) on \( U_{p} (p = 1, 2, \cdots, N). \) On this account, we can deduce that

\[
B = \int_{D \cap (\bigcup_{p=1}^{N} U_{p})} \left( \sum_{i=1}^{d} \left| \frac{\partial h_{N}}{\partial x_{i}} \right| \right)^{\gamma(\alpha)} dx \leq C(\gamma) \sum_{p=1}^{N} \sum_{i=1}^{d} \int_{D \cap U_{p}} \left| \frac{\partial h_{N}}{\partial x_{i}} \right|^{\gamma(\alpha)} dx \\
\leq C'(\gamma, d) \sum_{p=1}^{N(\varepsilon)} a_{d-\gamma(\alpha)}^{1} \leq C'(\gamma, d),
\]

by employing (d) of Lemma 4 and the condition (iii) of the covering \( \{G_{i}^{[\varepsilon]}\} \) of \( K. \) Next let us consider the integral \( I_{12*} = \int u \cdot g \sum_{i,j} a_{ij} (\partial_{ij} h_{N}) \) \( dx. \) Since \( g \in C^{1,1}(\bar{D}), \) we can estimate similarly

\[
I_{12*} \leq C \|g/p\|_{\infty} \int_{D} u \sum_{i,j} \partial_{ij} h_{N} p(x) dx \leq C_{1} \|u\|_{L^{\alpha}(\mu)} \cdot \left( \int_{D} \sum_{i,j} \partial_{ij}^{2} h_{N} \right)^{\beta} \mu(dx))^{1/\beta}
\]

by making use of Hölder’s inequality with \( 1/\alpha + 1/\beta = 1. \) The same discussion in estimating (10) is valid, too, for (11). \( \int_{D \cap (\cup_{j=1}^{N} 2G_{j})} u^{\alpha} d\mu \) vanishes as \( \varepsilon \) tends to zero, because the covering \( \{G_{i}^{[\varepsilon]}\} \) is standard. Thus we attain that \( I_{12*} \to 0 \) as \( \varepsilon \to 0. \) The computation goes almost similarly for the rest of other terms. Consequently we obtain

\[
I_{1} \to \int_{D} u \sum_{i,j} (\partial_{ij} a_{ij}) \partial_{ij} g \) \( dx + \int_{D} u \sum_{i,j} a_{ij} \partial_{ij}^{2} g \) \( dx, \quad I_{2} \to \int_{D} u \sum_{i} \partial_{i} g \) \( dx, \quad I_{3} \to \int_{D} c \cdot g \) \( dx \) as \( \varepsilon \to 0. \) This concludes the assertion (cf. [Dk98b]).

Let \( 1 < \alpha \leq 2 \) because of the restriction on the corresponding process in the probability theory which we are relying on. From the argument in Theorem 1, the existence of singularity is allowed if \( d > \gamma(\alpha) \) for \( \alpha > 1. \) It is well known that the sets \( A \subset \mathbb{R}^{d} \) with \( \dim_{H}(A) > d - \gamma(\alpha) \) cannot be S-polar. Corollary in Dynkin(1991) suggests that \( \partial \)-polar \( K \) is the RBS together with Theorem 2, because the S-polarity induces the \( \mathcal{R} \)-polarity and then \( \dim_{H}(K) < d - \gamma(\alpha). \) We call \( \beta = d - \gamma(\alpha) \) the critical dimension for \( \mathcal{R} \)-polarity.
We write $\text{Cap}_{x}^{D}$ for the capacity on the boundary $\partial D$ associated with the range $\mathcal{R}(\tilde{X}_{D})$ under the measure $P_{x}$. As a matter of fact, by Choquet’s capacity theory, $\Gamma$ is $\partial$-polar iff $\text{Cap}_{x}^{D}(\Gamma) = 0$ for all $x \in D$. While, for the Bessel capacity $\text{Cap}_{r,p}$, the class of $\mathcal{R}$-polar sets for any $(L, \alpha)$-superdiffusion $X$ is identical to the class of null sets of the capacity $\text{Cap}_{2, (\frac{\alpha}{\alpha - 1})}$. Based upon this result, it can be deduced that the class of $\partial$-polar sets is the same as the class of null sets for the Poisson capacity $\text{Cap}^{L}_{\alpha/(\alpha - 1)}$, where
\[
\text{Cap}^{L}_{\alpha/(\alpha - 1)}(F) := \sup \left\{ \nu(F); \int m(dx) \left[ \int_{F} k_{L}(x, y) \nu(dy) \right]^{\frac{\alpha}{\alpha - 1}} \leq 1 \right\}
\]
for a compact set $F$ with $\nu \in M_{F}(K)$ and an admissible measure $m(dx)$ on $D$ (cf. Theorem 1.2a, [DK96]). Moreover, the above-mentioned class also coincides with the class of null sets for the Riesz capacity $\text{Cap}^{D}_{o, \alpha/(\alpha - 1)}$. According to the Dynkin-Kuznetsov general theory for the removability of singularity, we can show that $\Gamma$ is a weak RBS if $\text{Cap}^{D}_{o, \alpha/(\alpha - 1)}(\Gamma) = 0$. Since every weak RBS is $\partial$-polar, the assertion of Theorem 3 is established via the argument on the explicit representation of solution $u(x) = -\log P_{x, \alpha} \exp\left(-\langle \overline{x}, \tau' f \rangle \right)$ to the problem (1), where $\overline{X}_{\tau}(B) := X_{\tau}(\mathbb{R}^{+} \times B)$, $\forall B \in \mathcal{B}(\mathbb{R}^{d})$ with the first exit time $\tau$ from $D$ (cf. Dynkin(1991), [Dk98c]).

Acknowledgement. The results presented in this article was announced in the Workshop on Nonlinear Partial Differential Equations 1998, held at the Department of Mathematics, Faculty of Science, Saitama University, during September 21-22, 1998. The author is very grateful to Professor Shigeaki Koike (Saitama University) for giving him a chance to talk in the above-mentioned international conference.
