25. Studies on the Rate of Reaction CH₄ and CO₂. (III)

Kimio Tarama and Syüichi Hayakawa
(Kodoma Laboratory)

The rate of thermal reaction of CH₄ and CO₂ was investigated at 1147–1236°K and 100–300 mmHg in which the pressure change caused by the reaction was determined and the reaction product was analysed with a modified Ambler's apparatus.

In the earlier stage of the reaction, H₂ is mainly formed, as the result of a mere decomposition of CH₄ and in the later stage CO is formed due to the reaction of CO₂ and H₂ which increased rapidly as the reaction proceeds, but the amounts of CO are always smaller than those of H₂.

At constant initial pressures of CH₄, the amounts of H₂ produced are scarcely affected by the initial pressures of CO₂, but contrarily those of CO change regularly with the initial CO₂ pressure. On the other hand, both amounts of H₂ and CO increase conspicuously with the initial CH₄ pressure when the initial pressures of CO₂ are constant.

In the earlier stage of the reaction, the rate of pressure change is the 1st order with respect to the partial pressure of CH₄, while the rate of CO formation is always approximately 1st order respecting partial pressure of CO₂.

On the basis of the results of these experiments and the previous investigations on the rates of the reaction of CO₂+H₂=CO+H₂O and C+CO₂=2CO, the following mechanism is proposed:

\[ k_1 \]
\[ CH_4 \rightarrow C \ (ad) + 2H_2 \]

\[ k_2 \]
\[ CO_2 \leftrightarrow CO_2(ad) \]

\[ k_3 \]
\[ CO_2(ad) + H_2 \rightarrow CO + H_2O(ad) \]

\[ k_4 \]
\[ C(ad) + H_2O(ad) \rightarrow CO + H_2 \]

(86)
\[ k_5 \]

\[ C(\text{ad}) + \text{CO}_2(\text{ad}) \rightarrow 2\text{CO} \]

\[ k : \text{velocity constant} \]

(ad): represents the adsorbed state on the reaction vessel surface.

The following equation for the rate of CO formation can be derived from this mechanism with the assumptions that the adsorption of CO$_2$ exists always in an equilibrium and $k_5 \ll k_3 \ll k_4$,

\[
\frac{d[\text{CO}]}{dt} = \frac{2k_5[H_2]}{r_2/k_3 + [H_2]}[\text{CO}_2],
\]

which reproduces our experimental results approximately.

26. Syntheses of Antioxidants for Fats and Oils. II
Cresol-analogs of NDGA and Polynuclear Phenolic Antioxidants

Keiiti Sisido and Hirosi Kuyama
(Sisido Laboratory)

The two cresol-analogs of NDGA were prepd. The Grignard reagent of p-bromo-o-cresol methylether was condensed with allyl bromide to p-methoxy-m-methylallylbenzene (I), $b_1$ 132-142°. The Grignard reagent of the hydrobromide of (I), $b_1$, 132-140°, was treated with $I_2$, giving meso and racemic mixt. of 1,4-bis (p-methoxy-m-methylphenyl)-2,3-dimethylbutane, $b_2$ 210-215°, meso m. 79-80°. On demethylation with MeMgI and recryst. from benzene, free phenol (II), m. 80-81°, was obtained. p-Cresol allyl ether was rearranged and then methylated to 2-methoxy-5-methylallylbenzene (III), $b_3$ 131-132°. Hydrobromide of (III), $b_3$, 138-142°, was treated as above, giving 1,4-bis(2-methoxy-5-methylphenyl)-2,3-dimethylbutane, $b_4$, 195-200°, meso m. 91°, free phenol (IV) m. 163-4°.

The following hindered phenol antioxidants having large molecular size were prepd. The mixt. of 10 g. of 2,6-dimethylol-p-cresol and 39 g. of phenol in 50 ml. of 60% ethanol was saturated with HCl gas at 0°. On standing overnight there resulted white crystals which were filtered and 12 g. of condensate (V), recryst. from acetic acid m. 211-12°, acetate m. 117-18°, was obtained. The determination of the structure is now under way. 2,6-Dimethylol-p-cresol and p-cresol gave crystalline condensate (VI), m. 210-11°, which has probably a four nuclear cyclic structure according to J. B. Niedrel (J. Am. Chem. Soc. 65 629 (1943)). On similar treatments o-cresol, thymol and eugenol gave amorphous solids (VII), (VIII) and
