On the Mechanisms of Reactions of Ketene with Compounds Containing an Active Methylene Group or with Phenols

Toshizo ISOSHIMA*
(Nodzu Laboratory)
Received April 17, 1956

In previous papers of this series, experimental results of the reactions of ketene with compounds containing an active methylene group such as ethyl acetoacetate, acetylacetone, diethyl malonate and ethyl cyanoacetate, or with phenols such as phenol, resorcinol, phloroglucinol and dimeredone, were shown.

When the reactions under ice-cooling or warming on a steam-bath were performed in various conditions, that is to say, without catalyst, using sodium salts of the above-mentioned compounds or in the presence of sulfuric acid, pyridine or some other organic bases, the C-acetyl derivatives or the O-acetyl derivatives of them were obtained according to the reaction conditions.

In this paper, these experimental results are summarized, and the reaction mechanisms of C-acetylation and O-acetylation with ketene are discussed.

Experimental results reported in parts I-IV\(^3,4,12\) of this series are summarized in Table 1. Those in part V\(^5\) and part VI\(^6\) are shown in Table 2 and Table 3, respectively.

Canonical structures* of ketene are as follows:

$$\begin{align*}
\text{H}_2\text{C}=\text{C}=\text{O} & \rightarrow \text{H}_2\text{C}=\text{C}-\text{O}\text{H} \\
\text{H}_2\text{C}=\text{C}=\text{C}=\text{O} & \rightarrow \text{H}_2\text{C}=\text{C}-\text{O} \\
\text{H}_2\text{C}=\text{C}=\text{C}=\text{O} & \rightarrow \text{H}_2\text{C}=\text{C}-\text{O}\text{H}
\end{align*}$$

Formula (1) has been used very often to explain the reactions of ketene. For example, the process of reaction of ketene with hydrogen cyanide \((K_A = 4.79 \times 10^{-10}, 18^\circ\text{C})\)\(^{10}\) is as follows:\(^{11}\)

$$\begin{align*}
\text{CH}_2=\text{C}=\text{O} + \text{HCN} & \rightarrow \text{CH}_2=\text{C}-\text{O} \\
& \rightarrow \text{CH}_2=\text{C}-\text{OH} \\
& \rightarrow \text{CH}_2=\text{C}=\text{O} \\
& \rightarrow \text{HC} = \text{O} \text{CN} \\
& \rightarrow \text{HC} = \text{O} \text{CN}
\end{align*}$$

In this reaction, ketene reacts as a base. From this point of view, in which ketene reacts as a base, reactions of ketene with compounds containing an active methylene group or with phenols will be considered.

Reactions of Ketene with Active Methylene Compounds

(1) THE MECHANISMS OF REACTIONS WITHOUT CATALYST

Mechanisms of reactions without catalyst will be considered.

The $PK_A$ values of the compounds used in the experiments are shown in Table 4.

</tr>
</tbody>
</table>

At first, to explain the mechanism of reactions of ketene with compounds containing an active methylene group without catalyst, for example, the reaction of ketene with ethyl acetoacetate will be considered.

Ethyl acetoacetate exhibits keto-enol tautomerism.\cite{14} The enol content at equilibrium (at 20°C) was 7.4% according to the bromination method devised by K. H. Meyer.\cite{13} It was already proved by infrared spectrum\cite{16} that the enol form was stabilized by the following intramolecular hydrogen bond and conjugated system.

\[
\begin{array}{c}
\text{CH}_3\text{C} \equiv \text{CHC} &=& \text{OC}_2\text{H}_5 \\
\text{O} \equiv \text{H} \quad \text{O} \\
(\text{I}), \text{(keto form)} &\quad & (\text{II}), \text{(enol form)}
\end{array}
\]

Therefore, when ketene is passed into ethyl acetoacetate, ketene does not react with the enol form which is stabilized to the extent of some 5-10 kcal./mole by the hydrogen bond\cite{17} and to the extent of some 2-3 Kcal./mole by the conjugated system,\cite{17} but reacts with the keto form which is more polar\cite{18} ($PK_A = 10.7$) than the enol form, that is to say, has a stronger ionization tendency of C-H in the active methylene group.

As soon as ketene takes a proton from the active methylene group, the formed carbonium cation combines with the carbanion (IV), which is formed by loosing a proton, and through the intermediate (V), the C-acetyl derivative (VI), of ethyl acetoacetate is obtained.
The above-mentioned reaction mechanism is shown by the following formulas:

\[
\begin{align*}
\text{CH}_3\text{C} & \text{H}_2\text{C} = \text{C} \text{O} \text{C}_2\text{H}_5 & \text{CH}_2\text{C} & = \text{C} \text{O} \text{C}_2\text{H}_5 \\
\text{O} & \text{O} & \text{O} & \text{O} \\
\text{I} & \text{II} & \text{III} & \text{IV} \\
\end{align*}
\]

Behaviours of acetylacetone are the same as those of ethyl acetoacetate and ketene does not react with the stabilized enol form, but does with the keto form to give the C-acetyl derivative.

The PK, value of active methylene group of acetylacetone is 9.3, that is to say, the ionization tendency of C-H in the active methylene group is greater than that of ethyl acetoacetate, therefore it is natural that the C-acetyl derivative is obtained even at a low reaction temperature. The ionization tendency of C-H in the active methylene group of diethyl malonate (PK, = 12.9) or ethyl cyanoacetate (PK,  12.9) is respectively smaller than that of ethyl acetoacetate and it is not strong enough to give a proton to ketene, therefore no reaction occurs.

Next, to explain the mechanism of reactions of ketene with phenols, for example, the reaction of ketene with phenol (VII) will be considered. The PK, value of phenol is 9.9. Soon after ketene is passed into phenol and takes a proton from the latter, like in the reaction of ketene with ethyl acetoacetate, the formed carbonium cation combines with the oxygen of the phenolate ion (VIII) which has been formed by losing a proton. Then, through the intermediate (IX), the O-acetyl derivative (X) of phenol is obtained. The abovementioned reaction mechanism is shown by the following formulas:

\[
\begin{align*}
\text{OH} + \text{CH}_3\text{C} = \text{C} \text{O} \\
\text{(VII) I} \\
\end{align*}
\]
Reactions of Ketene with Active Methylene Compounds

\[
\begin{align*}
\text{CH}_3\text{C}=\text{C} & - \text{CH} \quad \text{Na}^+ + \text{CH}_2=\text{C}=\text{O} \\
\text{CH}_2=\text{C} & - \text{CH} = \text{CH}_3 + \text{CH}_2=\text{C}=\text{O} \quad \text{Na}^+ \\
\end{align*}
\]

The O-acetyl derivatives of resorcinol, phloroglucinol and dimerone are respectively formed by the same mechanism as the O-acetyl derivative of phenol is formed.

(2) THE MECHANISMS OF REACTIONS OF KETENE WITH SODIUM SALTS OF COMPOUNDS CONTAINING AN ACTIVE METHYLENE GROUP OR WITH SODIUM SALTS OF PHENOLS

At first, to explain the mechanism of reactions of ketene with sodium salts of compounds containing an active methylene group, for example, the reaction of ketene with sodium salt of acetylacetone will be considered.

In the reaction of ketene with the sodium salt (I)\textsubscript{2} of acetylacetone, ketene takes a sodium cation from the salt and forms the carbonium cation (III)\textsubscript{2}. On the other hand, the negative ion (II)\textsubscript{2} is given by losing a sodium cation from the salt and it has a resonance system.

\[
\begin{align*}
\text{CH}_3\text{C}=\text{C} & - \text{CH} \quad \text{Na}^+ + \text{CH}_2=\text{C}=\text{O} \\
\text{CH}_2=\text{C} & - \text{CH} = \text{CH}_3 + \text{CH}_2=\text{C}=\text{O} \quad \text{Na}^+ \\
\end{align*}
\]

Next, the distribution of electron density in the negative ion (II)\textsubscript{2} will be considered. According to Yonezawa's calculation\textsuperscript{23} by the molecular orbital method, when a positive ion attacks the following resonance system,

\[
\text{C} - \text{C} - \text{C} - \text{C}
\]

the distribution of electron density is as follows:

\[
\begin{array}{cccc}
1/3 & 0 & 1/3 & 0 & 1/3
\end{array}
\]
On the basis of this calculation, when a positive ion attacks the following resonance system in which both terminal carbons of the above resonance system are replaced with oxygens,

\[
\text{O}^{-} - \text{C} = \text{C} - \text{C} - \text{O}
\]

the distribution of electron density is as follows:

\[
\text{O} - \text{C} - \text{C} - \text{C} - \text{O}
\]

\[
1/8 \quad 1/8 \quad 1/2 \quad 1/8 \quad 1/8
\]

So, when a positive ion attacks the resonance system (II)\textsubscript{2}, the electron density at the carbon of active methylene group is much larger than at the oxygen in (II)\textsubscript{2}. Therefore, when the carbonium cation (III)\textsubscript{2} attacks (II)\textsubscript{2}, it combines with the carbon of the active methylene group of (II)\textsubscript{2}, and through the intermediate (IV)\textsubscript{2}, the C-acetyl derivative (V)\textsubscript{2} of acetylacetone is formed.

\[
\text{CH}_3\text{C} = \text{CH} - \text{C} - \text{CH}_3 + \text{CH}_2\text{C} = \text{O} - \text{Na} \quad \text{(III)2}
\]

\[
\text{(II)2}
\]

\[
\text{CH}_3\text{C} = \text{CH} - \text{C} - \text{CH}_3
\]

\[
\text{O} \quad \text{O}
\]

\[
\text{Na}
\]

\[
\text{H}^+ \quad \text{(IV)2}
\]

\[
\text{CH}_3\text{C} = \text{CH} - \text{C} - \text{CH}_3
\]

\[
\text{O} \quad \text{O}
\]

\[
\text{(V)2}
\]

On the other hand, even if the carbonium cation (III)\textsubscript{2} combines with the oxygen in (II)\textsubscript{2} to give the O-acetyl derivative, its yield is very low.

The formation of the C-acetyl derivatives of ethyl acetoacetate, diethyl malonate and ethyl cyanoacetate are respectively interpreted by the same mechanism as the C-acetyl derivative of acetylacetone is formed.

Next, to explain the mechanism of reactions of ketene with sodium salts of phenols, for example, the reaction of ketene with sodium salt of phenol will be considered.

In the reaction of ketene with the sodium salt of phenol (VI)\textsubscript{2}, ketene takes a sodium cation from the salt, giving a carbonium cation (III)\textsubscript{2}. On the other hand,
Reactions of Ketene with Active Methylene Compounds

the phenolate ion (VII) which has been formed by loosing a sodium cation from
the salt, has a resonance system.

\[
\begin{array}{c}
\text{(VI)}_2 \\
\text{(VII)}_2
\end{array}
\]

\[
\begin{array}{c}
\text{\textbf{O}} \\
\text{\textbf{Na}} + \text{\textbf{CH}_2=\textbf{C}-\text{O}} \\
\text{\textbf{O}} + \text{\textbf{CH}_2=\textbf{C}-\text{ONa}} \\
\text{\textbf{O}} + \text{\textbf{O}}_2
\end{array}
\]

The canonical structures of this phenolate ion are as follows:

\[
\begin{array}{c}
\text{(i)} \\
\text{(ii)} \\
\text{(iii)} \\
\text{(iv)} \\
\text{(v)}
\end{array}
\]

The resonance energy of this phenolate ion is about 8 Kcal./mole greater than
that of phenol (39 Kcal./mole), therefore being 54 Kcal./mole.

Even if 15 Kcal./mole (54 Kcal./mole – 39 Kcal./mole) is quite due to the con-
tribution of (iii), (iv) and (v) to the resonance, it is much smaller than the
resonance energy of the benzene nucleus (39 Kcal./mole), so the contribution of (i)
and (ii) to the resonance of the phenolate ion is very large.

Therefore, the electron density at oxygen is largest, and the carbonium cation
(III) does not combine with the carbon, but with the oxygen in (VII). Thus,
through the intermediate (VIII), the O-acetyl derivative (IX) of phenol is formed.

\[
\begin{array}{c}
\text{\textbf{O}} + \text{\textbf{CH}_2=\textbf{C}-\text{ONa}} \\
\text{\textbf{O}} + \text{\textbf{CH}_2=\textbf{C}-\text{ONa}} \\
\text{\textbf{O}} + \text{\textbf{O}}_2 \\
\text{\textbf{O}} + \text{\textbf{O}}_2
\end{array}
\]

Even if (III) combines with the carbon in (VII), only a little of the C-acetyl
derivative is formed.

The O-acetyl derivatives of resorcinol, phloroglucinol and dimedone are re-
spectively formed by the same mechanism as the O-acetyl derivative of phenol is
formed.

(3) THE MECHANISMS OF REACTIONS IN THE PRESENCE OF SULFURIC ACID

At first, to explain the mechanism of reactions of ketene with compounds containing an active methylene group in the presence of sulfuric acid, for example, the reaction of ketene with ethyl acetoacetate will be considered. When ketene is passed into ethyl acetoacetate to which sulfuric acid is added as a catalyst, a proton lost from sulfuric acid combines with the oxygen of the carbonyl group in ketene and the carbonium cation (II)₃ is formed.

On the other hand, although the proton has a possibility to combine with the oxygen of carbonyl group in ethyl acetoacetate, they do not combine because of the chelate ring formed by the hydrogen bond. Therefore, through the complex compound (III)₃ which is formed by the reaction of ethyl acetoacetate with the carbonium cation (II)₃, the O-acetyl derivative (IV)₃ of ethyl acetoacetate is obtained. The above-mentioned reaction mechanism is shown in the following formulas:

\[
\begin{align*}
\text{(I)₃} & \quad \text{(II)₃} \\
\begin{array}{c}
\text{CH₃—C—CH₂—C—OC₂H₅} \\
\text{CH₃—C—C₄—CH₂—OC₄H₈}
\end{array} & + \begin{array}{c}
\text{CH₂═C═O} \\
\text{HO—C═CH₂}
\end{array} + \begin{array}{c}
\text{H₂SO₄} \\
\text{SO₄HΞ}
\end{array}
\end{align*}
\]

The O-acetyl derivative of acetylacetone is formed by the same mechanism as the O-acetyl derivative of ethyl acetoacetate is formed.

While, even if the O-acetyl derivatives of diethyl malonate and ethyl cyanoacetate are formed respectively by the same mechanism as the above, they are too unstable to be detected.

Then, to explain the mechanism of reactions of ketene with phenols in the presence of sulfuric acid, for example, the reaction of ketene with phenol will be considered.
Reactions of Ketene with Active Methylene Compounds

When ketene is passed into phenol to which sulfuric acid is added as a catalyst, ketene takes a proton from sulfuric acid, therefore the bisulfate anion and carbonium cation \((\text{II})_3\) are formed respectively.

On the other hand, as phenol gives a proton to the bisulfate anion, the phenolate ion \((\text{V})_3\) having a resonance system is formed. Then, the O-acetyl derivative of phenol is formed from \((\text{II})_3\) and \((\text{V})_3\).

The above-mentioned mechanism is shown in the following formulas:

\[
\begin{align*}
\text{Phenol} & \quad \text{H}_2\text{SO}_4 \quad \text{CH}_2=\text{C}=\text{O} \\
\text{Bisulfate anion} & \quad \text{H} + \text{SO}_4^2^- + \text{CH}_2=\text{C}=\text{O} \\
& \quad \text{(II)}_3 \\
\text{Phenolate ion} & \quad \text{H}_2\text{SO}_4 + \text{CH}_2=\text{C}=-\text{OH} \\
& \quad \text{(V)}_3 \\
\text{O-Acetyl derivative} & \quad \text{H}_2\text{SO}_4 + \text{CH}_2=\text{C}=-\text{OH} \\
& \quad \text{(VI)}_3 \\
\text{O-Acetyl derivative} & \quad \text{H}_2\text{SO}_4 + \text{CH}_2=\text{C}=-\text{OH} \\
& \quad \text{(VII)}_3
\end{align*}
\]

The O-acetyl derivatives of resorcinol are formed by the same mechanism as the O-acetyl derivative of phenol is formed.

(4) THE MECHANISMS OF REACTIONS IN THE PRESENCE OF PYRIDINE AND SOME OTHER ORGANIC BASES

At first, to explain the mechanisms of reactions of ketene with compounds containing an active methylene group in the presence of pyridine, for example, the reaction of ketene with ethyl acetoacetate will be considered. In the mixture of ethyl acetoacetate and pyridine, the following hydrogen bonds, \((\text{I})_4\) and \((\text{II})_4\), are presumed.

\[
\begin{align*}
\text{Ethyl acetoacetate} & \quad \text{N} \quad \text{H} \\
& \quad \text{(I)}_4 \\
\text{Pyridine} & \quad \text{H} \quad \text{(II)}_4
\end{align*}
\]

But the hydrogen bond \((\text{II})_4\) was denied by Le Fèvre,\(^{23}\) because it was proved...
by infrared spectrum that the enol content (4 %) of ethyl acetoacetate in pyridine is nearly equal to that (7.4 %) of pure ethyl acetoacetate.

While, in the mixture of chloroform and pyridine, the following hydrogen bond:

was proved by infrared spectrum or an addition compound presented by the freezing point-composition diagram. The following hydrogen bond between o-chlorophenol and pyridine was also proved by the freezing point-composition diagram:

and moreover the $\text{PK}_a$ value of o-chlorophenol (10.1) is nearly equal to the $\text{PK}_a$ value of ethyl acetoacetate (10.7).

The above-mentioned results are sufficient to support the existence of the hydrogen bond (I).

Therefore, the intermediate (III) is formed from ketene and (I), and then after rearrangement of hydrogen in the intermediate (IV) which is given from (III), the O-acetyl derivative of ethyl acetoacetate is obtained. The O-acetyl derivative of acetylacetone is formed by the same mechanism as the O-acetyl derivative of ethyl acetoacetate is formed.
Reactions of Ketene with Active Methylene Compounds

\[
\begin{align*}
\text{CH}_3\text{—C—CH—COOC}_2\text{H}_5 \\
\text{O} \\
\text{CH}_3\text{—C—O} \\
\quad (\text{V})_4
\end{align*}
\]

On the other hand, some C—H fission of the active methylene group in (I)_4 occurs and a complex compound (VI)_4 is formed. The reaction of ketene with (VI)_4 gives an anion (VII)_4 and a cation (VIII)_4 from which a little of the C-acetyl derivative is obtained by the same mechanism as it is obtained from ketene and the sodium salt of ethyl acetoacetate.

\[
\begin{align*}
\text{CH}_3\text{—C—CH—C—OC}_2\text{H}_5 \\
\quad (\text{I})_4
\end{align*}
\]

\[
\begin{align*}
\left[\text{CH}_3\text{—C—CH—C—OC}_2\text{H}_5\right]^+ \\
\quad (\text{VI})_4
\end{align*}
\]

\[
\begin{align*}
\text{CH}_3\text{—C—CH—C—OC}_2\text{H}_5 + \text{CH}_2\text{—C—OH} + \text{N} \\
\quad (\text{VIII})_4
\end{align*}
\]

The experimental results of reactions of ketene with ethyl acetoacetate in the presence of some organic bases are shown in Table 2. Hydrogen bonds corresponding to (I)_4 are formed between ethyl acetoacetate and some organic bases shown in Table 2 respectively. As they are stable at low temperatures, much of the O-acetyl derivative and a very little of the C-acetyl derivative are formed by the above-mentioned mechanisms. While, at high temperatures, the hydrogen bond between ethyl acetoacetate and dimethylaniline or quinoline is unstable and because of fission of the hydrogen bond, the C-acetyl derivative is formed by the same mechanism as in case of no catalyst.

On the other hand, the stronger the basicity of the organic base (pyridine, triethyl amine, piperidine) is, the more the hydrogen bond corresponding to (I)_4 decreases and also the more the dissociation corresponding to (IV)_4 increases, and

(205)
therefore the more the C-acetyl derivative is formed.

The enol content (0.01%) of diethyl malonate is very small and this enol form has an intramolecular hydrogen bond (IX). This hydrogen bond (IX) is weaker than that of acetylacetone or ethyl acetoacetate, therefore the addition of pyridine causes fission of the hydrogen bond, giving an anion (X) and a hydropyridinium ion (XI). In the reaction of ketene with these ions, the C-acetyl derivative of diethyl malonate (XIII) is formed by the same mechanism as is seen in the reaction of ketene with the sodium salt of diethyl malonate.

With progress of the reaction, the keto form shifts to the enol form.

\[
\begin{align*}
\text{C}_2\text{H}_5\text{O} &- \text{C} - \text{CH} - \text{C} &- \text{OC}_2\text{H}_5 \\
\text{O} &- \text{H} &... &- \text{O} + \text{N} \\
\text{(IX)} &\downarrow & & & \\
\text{C}_2\text{H}_5\text{O} &- \text{C} - \text{CH} &- \text{COOC}_2\text{H}_5 \\
\text{O} &- \text{O} &+ \text{CH}_2=\text{C} &- \text{O} \\
\text{(X)} &\downarrow & & & \\
\text{C}_2\text{H}_5\text{O} &- \text{C} - \text{CH} &- \text{C} &- \text{OC}_2\text{H}_5 \\
\text{O} &- \text{O} &+ \text{CH}_2=\text{C} &- \text{OH} + \text{N} \\
\text{(XI)} &\downarrow & & & \\
\text{C}_2\text{H}_5\text{O} &- \text{C} - \text{CH} &- \text{C} &- \text{OC}_2\text{H}_5 \\
\text{O} &- \text{O} &+ \text{CH}_2=\text{C} &- \text{OH} \\
\text{(XII)} &\downarrow & & & \\
\text{C}_2\text{H}_5\text{OC} &- \text{CH} &- \text{COOC}_2\text{H}_5 \\
\text{CH}_3\text{CO} &- \text{N} \\
\text{(XIII)}
\end{align*}
\]

Two kinds of tautomerism, keto-enol and nitrile-ketenimide tautomerism, in ethyl cyanoacetate are as follows:

\[
\begin{align*}
\text{HN}=\text{C} &- \text{CH} - \text{C} - \text{OC}_2\text{H}_5 \rightleftharpoons \text{N} &- \text{C} - \text{CH}_2 - \text{C} - \text{OC}_2\text{H}_5 \rightleftharpoons \text{N} &- \text{C} - \text{CH} &- \text{C} - \text{OC}_2\text{H}_5 \\
\text{O} &- \text{O} &- \text{O} &- \text{H}
\end{align*}
\]

The atomic distance \( O \ldots N \) in the enol form or the ketenimide form of ethyl
cyanoacetate is larger than 3 Å, on the other hand, the atomic distance O···N in the hydrogen bond N···H—O is 2.6 Å, so hydrogen bond does not exist in ethyl cyanoacetate. Therefore, when pyridine is added to ethyl cyanoacetate, the former takes a proton from hydroxy group of the enol form and the imino group of the ketenimide form of the latter, and the anion corresponding to (X)₄ are formed.

In the reaction of ketene with these ions, the C-acetyl derivative of ethyl cyanoacetate is formed by the same mechanism as is seen in the reaction of ketene with the sodium salt of ethyl cyanoacetate.

It can be supposed that in the mixture of pyridine and diethyl malonate or ethyl cyanoacetate, besides the above-mentioned hydropyridinium ion, the hydrogen bond between the active methylene group and pyridine (C—H···N< ) is also formed. But, as the ionization tendency of C—H is small (PK₄ ≈ 12.9), the hydrogen bond is not formed. Even if the hydrogen bond is formed and in the reaction of ketene with the compound corresponding to (I)₄, the O-acetyl derivative is given by the same mechanism as the O-acetyl derivative of ethyl acetoacetate is formed, it cannot be detected because of its instability as in the reaction in the presence of sulfuric acid. While, the N-acetyl derivative of ethyl cyanoacetate should be formed theoretically, but it could not be obtained because of its instability or its very low yield.

Then, to explain the mechanism of reactions of ketene with phenols in the presence of pyridine, for example, the reaction of ketene with phenol will be considered.

In the mixture of phenol and pyridine, the hydrogen bond (XIV)₄ is formed. In the reaction of ketene with (XIV)₄, the O-acetyl derivative of phenol is given by the same mechanism as is seen in the reaction of ketene with sodium salt of phenol. The above-mentioned mechanism is shown in the following formulas:

\[
\text{The O-acetyl derivatives of resorcinol, phloroglucinol and dimedone are formed}
\]
Toshizo ISOSHIMA

respectively by the same mechanism as the O-acetyl derivative of phenol is formed.

ACKNOWLEDGMENT

The author wishes to express his sincere thanks to Professors R. Nodzu and S. Kunichika for their helpful discussion and encouragement in the study.

He also wishes to acknowledge his indebtedness to Shionogi & Co., Ltd. for its help.
