Glass Formation in the Systems (Na₂O, K₂O or BaO)-TiO₂-Al₂O₃

Tadashi KOKUBO and Megumi TASHIRO*

Received September 25, 1974

Glass-forming abilities of melts in the systems (R₂O or R'O)-TiO₂-Al₂O₃, where R is Li, Na or K and R' is Ca, Sr, Ba, or Pb, were examined with an ordinary crucible-melting technique, which consist of melting 15 g of raw materials in a Pt10%Rh crucible, pouring the melts onto a steel plate and pressing them into plates 1 mm thick. Clear glasses were obtained from some of the melts in the systems (Na₂O, K₂O, or BaO)-TiO₂-Al₂O₃. On the basis of X-ray emission spectroscopic and infrared spectroscopic analyses, the structures of the glasses obtained were inferred to be random networks consisting both of the A10₄ tetrahedra and TiO₆ octahedra in some holes of which are occupied by Na⁺, K⁺, or Ba²⁺ ions. The glass-forming abilities of the examined systems were interpreted in terms of the field strengths of R and R' ions situated in some holes of the network.

I. INTRODUCTION

Among aluminate melts containing no simple glass-forming oxides such as SiO₂, B₂O₃, P₂O₅, GeO₂, As₂O₃, and Sb₂O₃, the CaO-Al₂O₃ family is the only one heretofore known to form glass on a practically useful scale. Recently, however, the present authors have found that some aluminate melts in the systems (K or Cs)₂O-(Nb or Ta)₂O₅-Al₂O₃ also form fairly stable glasses.

In the present study glass-forming tendencies of the systems (R₂O or R'O)-TiO₂-Al₂O₃, where R is Li, Na, or K and R' is Ca, Sr, Ba, or Pb, were examined with an ordinary crucible-melting technique. Structures of the glasses obtained from these systems were also discussed on the basis of their X-ray emission spectra and infrared spectra.

Some melts in the binary systems containing TiO₂ or Al₂O₃, such as K₂O-TiO₂, CaO-TiO₂, SrO-TiO₂, BaO-TiO₂, PbO-TiO₂, SrO-Al₂O₃, BaO-Al₂O₃, and PbO-Al₂O₃ are already known to form glasses, if their melts are quenched in very small amounts and also extraordinarily rapidly by specially designed techniques such as a splat-quenching. The ternary systems investigated in the present study are combinations of these titanate and aluminate binary systems. Glass-forming tendencies of these ternary systems on a practically useful scale have not yet been investigated.

II. EXPERIMENTAL

1. Glass-Forming Tendency

For investigating glass-forming tendencies of the systems (R₂O or R'O)-TiO₂-
Al₂O₃, where R is Li, Na, or K and R' is Ca, Sr, Ba, or Pb, batch mixtures yielding various oxide compositions (mol %) shown in Fig. 1 were prepared from reagent grade chemicals of Li₂CO₃, Na₂CO₃, K₂CO₃, CaCO₃, SrCO₃, BaCO₃, Pb₃O₄, TiO₂.

Fig. 1. Glass-forming tendency.
○; Clear glass ∆; Partially devitrified glass ×; Fully devitrified glass *; Imperfect melt
and $\text{Al}_2\text{O}_3$. About 15 g of the batch mixtures were melted in a 50 ml Pt10%Rh crucible covered with a lid in a SiC furnace at 1550°C for 1 hr. The melts were poured onto a steel plate and pressed into plates approximately 1 mm thick. They were then quickly put into a preheated electric furnace, annealed at 400°–500°C for 30 min, and furnace-cooled.

All the resultant substances could be classified into the following four groups by observation with the naked eye and powder X-ray diffraction; clear glass, partially devitrified glass, fully devitrified glass and imperfect melt. The glass-forming tendencies of the compositions and the glass-forming regions are shown in Fig. 1, which indicates that fairly stable glasses can be obtained in the ternary systems $\text{Na}_2\text{O}-\text{TiO}_2-\text{Al}_2\text{O}_3$, $\text{K}_2\text{O}-\text{TiO}_2-\text{Al}_2\text{O}_3$, and $\text{BaO}-\text{TiO}_2-\text{Al}_2\text{O}_3$.

The glasses in the systems $\text{Na}_2\text{O}-\text{TiO}_2-\text{Al}_2\text{O}_3$ and $\text{BaO}-\text{TiO}_2-\text{Al}_2\text{O}_3$ had slight tinges of yellow and brown, respectively, whereas those in the system $\text{K}_2\text{O}-\text{TiO}_2-\text{Al}_2\text{O}_3$ had a strong tinge of brown. The $\text{Na}_2\text{O}$- and $\text{BaO}$-containing glasses were chemically fairly durable in a laboratory atmosphere, whereas the $\text{K}_2\text{O}$-containing glasses were extremely hygroscopic.

2. X-Ray Emission Spectroscopic Analysis

In order to determine the coordination number of $\text{Al}^{3+}$ ions in the glasses, the glasses of the compositions given in Table 1 were subjected to X-ray emission spectroscopic analyses. The X-ray emission spectra of $\alpha-\text{Al}_2\text{O}_3$ and K-feldspar crystals, which contain six-fold and four-fold coordinated $\text{Al}^{3+}$ ions, respectively, were measured as references.

The $\text{AlK}\alpha$ emission spectra of these specimens were recorded on a Rigaku Denki Geigerflex KG-4 X-ray fluorescence spectrometer with a chromium target at 50 KV and 40 mA. The EDDT analyzing crystal, a soller slit with dispersion angle of 0.15 and a gas-flow proportional counter with a pulse height analyzer were used. A vacuum of 0.1–0.2 torr was maintained to reduce the absorption of the emitted $\text{AlK}\alpha$ radiation. The scanning speed was 0.25° (2θ)/min. The chart speed was chosen so that 1° (2θ) was equivalent to 16 cm on a chart paper. Recording of the glass specimens and of the reference materials were alternated so that any drift in the recording process could be taken into account. The positions of their $\text{AlK}\alpha$ peaks were determined at 90% maximum intensity of the recorded peaks with respect to that for Al metal.

(635)
Fig. 2. Chemical shifts of AlKα peaks for (Na2O, K2O, or BaO)-TiO2-Al2O3 glasses.

The results are shown in Fig. 2 as a function of Al/(Na, K, or Ba) atomic ratio in the glasses. The position of the AlKα peak for glass 6 containing a large amount of BaO could not be determined since its weak AlKα peak lay upon a tail of a strong BaLα peak. It can be seen from Fig. 2 that the AlKα peaks of the glasses almost coincide in position with that of K-feldspar containing the tetrahedrally coordinated Al³⁺ ions, irrespective of the compositions of the glasses.

3. Infrared Spectroscopic Analysis

In order to investigate the coordination number of the Ti⁴⁺ ions in the glasses, infrared absorption spectra of all the glasses given in Table I were measured with a double-beam automatic infrared spectrometer (Perkin-Elmer 521) by a KBr disc method. The infrared absorptions of BaTiO₃ crystals prepared by a solid state reaction and the K₂O·2TiO₂ glass prepared by the splat-quenching technique were also measured as references. Both of them were already confirmed to contain six-fold coordinated Ti⁴⁺ ions by X-ray diffraction technique. The results are presented in Fig. 3. All of the (K₂O, Na₂O, or BaO)-TiO₂-Al₂O₃ glasses show a wide absorption bands extending from 900 to 500 cm⁻¹.

4. Comparison of Glass-Forming Regions Determined by Splat-Quenching and Crucible-Melting Techniques

For comparing the glass-forming region in the system BaO-TiO₂-Al₂O₃ determined by the crucible-melting technique with that determined by the splat-quenching technique, glass-forming tendency of the binary systems TiO₂-Al₂O₃ was examined by the splat-quenching technique. Glass-forming tendencies of the binary systems BaO-TiO₂ and BaO-Al₂O₃ were already determined by the splat-quenching technique by Sarjeant et al. Batch mixtures yielding various mol ratio of Al₂O₃/TiO₂ were prepared from reagent grade Al₂O₃ and TiO₂ and heated at 1500°C for 6 hr. About 0.1 g of the resultant materials were melted on an iridium strip heater at 1800°C-2000°C and blown off by a compressed oxygen gas against a microscope slide held at room temperature by using a splat-quenching apparatus similar to that described by Sarjeant et al. The quenched materials were subjected to X-ray diffraction analysis and observed under a polarizing microscope. The results indicated that none

of the compositions in the system TiO$_2$-Al$_2$O$_3$ could be fully vitrified by the splat-quenching technique. This result is represented in Fig. 4 together with the results for the systems BaO-TiO$_2$ and BaO-Al$_2$O$_3$ obtained by Sarjeant et al. The glass-forming region determined by the crucible-melting technique is reproduced in the same figure. The glass-forming region determined by the crucible-melting technique is located in both of the composition triangles formed by joining the both extremes of each binary glass-forming region on the sides AlO$_1$-BaO and BaO-TiO$_2$ to another end member as shown in Fig. 4.

III. DISCUSSION

A certain relation exists between the coordination number of Al$^{3+}$ ions in oxides and the positions of AlK$\alpha$ radiation peak. The positions of the AlK$\alpha$ radiation of the aluminate glasses determined by the X-ray emission spectroscopic analyses in the present study were found to coincide with that of the K-feldspar containing tetrahedrally coordinated Al$^{3+}$ ions, which indicates that the Al$^{3+}$ ions in the glasses are also tetrahedrally coordinated with oxygen ions.

The AlO$_4$ tetrahedra were reported to give an infrared absorption band at wave number of 900-650 cm$^{-1}$. The corresponding absorption band is observed on all the infrared spectra of the aluminate glasses obtained in the present study. However, the absorption band of the glasses is not limited in this region, but extend to the region of wave number from 650 to 500 cm$^{-1}$ as shown in Fig. 3. The latter region corresponds to the absorption band produced by the presence of TiO$_6$ octahedra as reported by Tarte. Therefore, a fairly large amount of the Ti$^{4+}$ ions are concluded to be octahedrally coordinated in the aluminate glasses.

The amounts of the Al$_2$O$_3$ in the aluminate glasses obtained in the present study might not be sufficient to form the three-dimensional network of the glasses with only the AlO$_4$ tetrahedra. Accordingly, the AlO$_4$ tetrahedra and the TiO$_6$ octahedra would cooperate in forming the network of the glasses, as shown in Fig. 5. The other ions such as Na$^+$, K$^+$, or Ba$^{2+}$ ions will sit in some holes of the network.

![Structure of K$_2$O-TiO$_2$-Al$_2$O$_3$ glass.](image)

It can be seen from Fig. 1 that the glass-forming ability of the system (R$_2$O or R'O)-TiO$_2$-Al$_2$O$_3$ is greatly affected by the type of R or R' ion, where R and R' are mono- and divalent cation, respectively. Its cause is interpreted as follows.

Each of the Al$^{3+}$ and Ti$^{4+}$ ions in these glasses forms an AlO$_4$ tetrahedron and TiO$_6$ octahedron, respectively, using one and two extra oxygen ions accompanied...
Glass Formation in the Systems (Na₂O, K₂O, or BaO)-TiO₂-Al₂O₃ by an R or R’ ion, together with three and four oxygen ions originally accompanied by itself. In such tetrahedral or octahedral structures, electron clouds in the binding region between the bridging oxygen core and Al or Ti core would be more strongly attracted toward the R or R’ ions, as the field strength of the R or R’ ion increases. This would weaken the binding forces in the glass network, thus facilitating crystallization in the glasses. The ionic field strengths given by \( Z_i/(r_i+r_o)^2 \) are listed in Table II for all the R and R’ ions introduced into the present systems, where \( Z_i, r_i, \) and \( r_o \) are the charge and radius of the R or R’ ion and the radius of the oxygen ion, respectively. The ionic field strength increases in the order \( K^+ < Na^+ < Li^+ < Ba^{2+} < Pb^{2+} < Sr^{2+} < Ca^{2+} \). The high glass-forming ability of the systems (K₂O, Na₂O, or BaO)-TiO₂-Al₂O₃ as well as the low glass-forming ability of the systems (PbO, SrO, or CaO)-TiO₂-Al₂O₃ systems, both confirmed by the present experiments, can thus be explained. The system Li₂O-TiO₂-Al₂O₃, is, however, an exception: Although the Li⁺ ion has the field strength lower than that of the Ba²⁺ ion, the glass-forming ability of the system Li₂O-TiO₂-Al₂O₃ was found to be rather low. This would be attributed to the special electron configuration of the Li⁺ ion compared to that of the other ions: The former is of the helium-type whereas the latter is of the neon-type. The ions having the helium-type electron configuration are known to be able to penetrate easily into the electron cloud of the polarizable oxygen ions in glasses, thus giving unusual effects on many properties of the glasses.

### IV. SUMMARY

Clear glasses could be obtained from some melts in the systems (Na₂O, K₂O, or BaO)-TiO₂-Al₂O₃ by an ordinary crucible-melting technique.

From the results of X-ray emission spectroscopic and infrared spectroscopic analyses, the structures of the glasses were inferred to be random networks consisting of the AlO₄ tetrahedra and TiO₆ octahedra in some holes of which Na⁺, K⁺, or Ba²⁺ ions are situated.

The high glass-forming abilities of the Na₂O-, K₂O-, and BaO-containing systems were ascribed to the low ionic field strength of the Na⁺, K⁺ or Ba²⁺ ion.
