Electron Paramagnetic Resonance Studies of Cobalt (II)
Thioiminato Schiff Base Compound with Lewis
Bases and Its Oxygen Adducts

Matsuiro Sakurada, Yoshihiro Sasaki, Masakazu Matsui,
and Tsunenobu Shigematsu

Received October 14, 1977

EPR spectra were observed for N,N'-ethylenediaminomonoothioacetylacetoneiminato-cobalt (II), Co(sacac)_{2}en, with the Lewis bases, LB, (pyridine, 4-methylpyridine, 4-cyanopyridine, piperidine, N-methylimidazole and N,N-dimethylformamide) and their oxygen complexes. The EPR spectra show that all of the Co(sacac)_{2}en(LB) complexes have the rhombic symmetry with (d_{x}^{2}-d_{y}^{2}, d_{z}^{2})^{9-}(d_{x}d_{y})^{1} ground configuration. Cobalt-59 hyperfine coupling constants are utilized in evaluating the unpaired electron spin distribution. The total cobalt spin densities are found to fall in the range of 0.66-0.78 and to be mainly localized on the cobalt atom for Co(sacac)_{2}en(LB). Co(sacac)_{2}en(LB) forms a monomeric 1:1 complex with molecular oxygen reversibly. It is found that the EPR parameters of the oxygen adducts are very similar for these Lewis bases.

INTRODUCTION

Low-spin cobalt (II) complexes with Schiff bases and porphyrins have recently received considerable interest because of their ability to form monomeric complexes with molecular oxygen reversibly.\(^1\,\text{a}-\text{b}\) Nitrogen donor adducts and their oxygenated complexes have been particularly investigated to understand the transport of molecular oxygen and oxidation by it in biological systems.\(^6\,\text{a}-\text{b}\) But little is known about the corresponding complexes with Schiff bases containing sulphur atom. It appears clearly that the behavior of the complexes containing sulphur atom is specific for the redox reaction from the recent studies of Ferredoxin and its related complexes.\(^9\,\text{a}-\text{b}\) Therefore, it is significant to study the role of sulphur atom for the electron transfer reaction; Co (II) + O\(_{2}\) = Co(III)O\(_{2}\).\(^-\)

We report on EPR studies for N,N'-ethylenediaminomonoothioacetylacetoneiminato-cobalt (II), Co(sacac)_{2}en, with nitrogen donors and discuss the results on the basis of the unpaired electron confined in a cobalt-nitrogen \(\sigma\) molecular orbital. Cobalt-59 hyperfine constants are used in evaluating the unpaired electron distribution. The reversible monomeric Co(sacac)_{2}en(LB)O\(_{2}\) complexes are reported and found to have similar magnetic parameters for various axial ligands.

EXPERIMENTAL

Materials. The synthesis of N,N'-ethylenediaminomonoothioacetylacetoneimine, H\(_{2}\)(sacac)\(_{2}\)
H$_2$(sacac)$_2$en was prepared by substitution of the oxygen atom of N,N'-ethylenebis-acetylacetoneimine, H$_2$(acac)$_2$en, to sulphur atom.$^{13}$ Triethylxonium tetrafluoroborate, (Et$_3$O)$^+$ (BF$_4$)$^-$, (0.1 mol) dissolved in dichloromethane (50 ml) was added to a solution of H$_2$(acac)$_2$en (0.05 mol) in dichloromethane (100 ml) with stirring under an atmosphere of nitrogen. After addition was complete, the mixture was more stirred for an additional 30 min. At the end of this time, a fine suspension of excess NaHS in ethanol was added to mixture. This mixture was stirred for 60 min and filtered to remove the insoluble sodium tetrafluoroborate. The filtrate was evaporated to dryness in vacuo and the crude ligand was recrystallized from acetone-water. (Found: C, 55.94; H, 8.09; N, 10.79%. Calcd for C$_{12}$H$_{20}$N$_2$S$_2$: C, 56.20; H, 7.86; N, 10.93%.)

H$_2$(acac)$_2$en and (Et$_3$O)$^+$ (BF$_4$)$^-$ were prepared according to the literatures.$^{13,14}$

The synthesis of Co(sacac)$_2$en. This complex was prepared under an atmosphere of nitrogen. Cobalt acetate tetrahydrate (0.01 mol) and H$_2$(sacac)$_2$en (0.01 mol) were dissolved in methanol (100 ml). The solution was warmed for 30 min on a steam bath and then cooled overnight in the refrigerator. The complex was obtained as red crystals. (Found: C, 45.90; H, 6.06; N, 8.73%. Calcd for C$_{12}$H$_{18}$N$_2$S$_2$Co: C, 46.00; H, 5.79; N, 8.94%.)

Pyridine, 4-methylpyridine, 4-cyanopyridine, piperidine, N-methylimidazole, and N,N-dimethylformamide were purchased commercially.

Measurements. The EPR spectra of the complex were measured in toluene containing a proper quantity of the Lewis base (LB) at 77 and 193 K. Prior to a measurement, each sample was degassed thoroughly. These samples could be oxygenated by exposure to oxygen gas ca —20°C more than 20 min.

**RESULTS AND DISCUSSION**

EPR spectra of Co(sacac)$_2$en with nitrogen donors. The EPR spectrum of Co(sacac)$_2$en in 10% pyridine-toluene at 77 K is shown in Fig. 1. The spectrum has three components of g-factor, suggesting that the Co(II) ion is placed in a rhombic symmetry. For the high field, seven of the eight $^{59}$Co ($I=7/2$) hyperfine lines are clearly resolved and several have been seen to be split into equally intensified triplet by the single $^{14}$N ($I=1$) of one axially coordinated pyridine molecule. A similar spectrum is observed in pyridine at 77 K. The samples with the other Lewis bases except N,N-dimethylformamide give
quantitatively identical spectra. This suggests that Co(sacac)\textsubscript{en} exists as a five coordinated complex, Co(sacac)\textsubscript{en}(LB), in these solutions.

The associated EPR parameters are listed in Table I. In each complex the g values and cobalt hyperfine coupling constants are consisted with a \((d_{x^2-y^2}, dxz, dyz)\)\((d_z^2)\) ground configuration. The magnetic parameters for this ground configuration are

\[
\begin{align*}
g_{xx} &= 2.002 - 6\lambda/\Delta E_{xx} \quad ^8 \\
g_{yy} &= 2.002 - 6\lambda/\Delta E_{yy} \quad ^8 \\
g_{zz} &= 2.002 \\
A_{xx} &= P[-k - 2/7 + (g_{xx} - 2.002) + 1/14(g_{yy} - 2.002)] \\
A_{yy} &= P[-k - 2/7 + (g_{yy} - 2.002) + 1/14(g_{xx} - 2.002)] \\
A_{zz} &= P[-k + 4/7 + 1/14(2.002 - g_{xx} + 2.002 - g_{yy})]
\end{align*}
\]

where \(\lambda\) is the effective spin-orbit coupling constant in the complex.\(^{13}\) \(\Delta E\) values are the energy separations of between \(d_{xz}, d_{yz},\) and \(d_{z^2},\) and \(Pk\) is the Fermi contact term.

A: 10⁻⁴ cm⁻¹

a) P and k values are based upon a (dₓ²−y², dₓz, dᵧz)⁶(dₓᵧ)⁴ ground configuration for cobalt (II).
b) A₀ and A₄ are the cobalt-59 contact and dipolar hyperfine constants corrected for orbital magnetism (A₀=-Pk, A₄=4/7P).
c) ρ₈d and ρ₄s are the spin densities in the cobalt 3d and 4s orbitals estimated from cobalt hyperfine constants.

Second-order contribution is not significant for Co(sacac)en(LB) where ΔEₓₓ+², ΔEᵧᵧ+², ΔEₜ=t²λ. The electronic parameters that result from solving these expressions for nitrogen donors are given in Table II. Using the observed gₓₓ, gᵧᵧ and the dₓₓ, dᵧᵧ → dₓ² energy separations, an effective spin-orbit coupling constant reduced from the free Co(II) ion value (λ₀=-515 cm⁻¹) is obtained. The cobalt P value reduced from the free ion value (P₀=0.023) permits the evaluation of the cobalt hyperfine constants, which is estimated according to the equation, P=P₀λ₀/λ₀. The reduction of the cobalt P value and the effective spin-orbit coupling constant from the free ion values is largely caused by the redistribution of the unpaired electron from the dₓ² to the σ donor orbital of the axial ligand.

Cobalt 3dₓ² spin density (ρ₈d) is estimated from comparison of the observed dipolar coupling constant (A₄) with the theoretical value (A₄=4/7P₀=0.01314 cm⁻¹) for a cobalt 3d electron. Cobalt 4s spin density (ρ₄s) is estimated from the Symons' equation.

$A: 10^{-4}$ cm$^{-1}$

a) $A_2$ values are calculated from $A_2 = 3A_{iso} - (A_1 + A_3)$.

$$A_{contact} = -P_k = \rho_{4s}A(\text{Co}4s) + \rho_{2d}(\text{Co}3d)$$

where $A(\text{Co}4s) = 0.1232$ cm$^{-1}$ and $A(\text{Co}3d) = -0.00840$ cm$^{-1}$.

The total cobalt spin density falls in the range 0.66 to 0.78 for this series of adducts, suggesting that the unpaired electron is mainly localized on the cobalt atom.

**EPR spectra of monomeric oxygen complexes.** The EPR spectra of the oxygenated Co(sacac)$_2$en(pyridine) in fluid and frozen toluene solutions are shown in Fig. 2 and the EPR parameters are tabulated in Table III. The oxygenated samples of the other bases give qualitatively identical spectra. These samples give the degassed spectra by exposure to nitrogen gas and the oxygenated spectra by exposing to oxygen gas again at low temperature. This indicates that the Co(sacac)$_2$en(LB) reversibly reacts with molecular oxygen.

The EPR spectra in the fluids split into eight lines due to a $^{59}$Co nucleus, which give the implication of the formation of a monomeric complex, Co(sacac)$_2$en(LB) (O$_2$). The spectra in frozen solutions split owing to a rhombic distortion, and then are complicated in perpendicular region. The $g$ values and hyperfine constants were similar for this series of
EPR Studies of Co(II)(sacac)\textsubscript{2}en with Lewis Bases and Its Oxygen Adducts

Co(sacac)\textsubscript{2}en'(LB). This insensitivity to the axial ligand may imply that the axial ligand plays the role of elevating the Co d\textsuperscript{2} orbital and assisting the electron transfer from Co atom to oxygen molecule, though it does not directly interact with unpaired electron of Co(sacac)\textsubscript{2}en(LB) (O\textsubscript{2}).

The degassed spectrum of Co(sacac)\textsubscript{2}en in frozen N,N-dimethylformamide-toluene solution is quite different from the other spectra (Fig. 3), while this sample exposed to oxygen gas gives qualitatively identical spectra with the other oxygenated complexes. The origin of the difference for the degassed spectra is being investigated at present.
