Kyoto University
Relativistic Calculations of the Excitation Cross Sections of Hydrogen-Like Ions by Heavy Charged-Particle Impact

Takeshi Mukoyama

Received February 4, 1986

The cross sections for excitation from the initial K shell to the final L1, L2, and L3 shells of hydrogen-like ions by heavy charged-particle impact have been calculated using the relativistic wave functions for the target electron in the plane-wave Born approximation. The calculated results are compared with the nonrelativistic calculations and the electronic relativistic effect is discussed.

KEY WORDS: Atomic Excitation/ Electronic Relativistic Effect/ Plane-Wave Born Approximation/

I. INTRODUCTION

The Coulomb excitation of atoms and ions by heavy charged-particle bombardment is of importance in atomic collision and its applications, such as plasma physics and astrophysics. However, this process has so far been much less investigated than the ionization and electron-capture processes in atomic collisions. In addition, almost all existing studies both theoretically and experimentally are limited to the case of excitation of hydrogen or helium by proton and α-particle impact. This is mainly due to experimental difficulties to obtain highly charged ions.

The theoretical calculations for atomic excitation cross sections have been performed in the plane-wave Born approximation (PWBA) and with impact-parameter approach. These works are nonrelativistic and useful for targets with low atomic numbers. To the author's knowledge, there has been reported no relativistic calculation for atomic excitation by heavy-particle impact, except for our previous work on the 1s–2s excitation cross sections.

With recent progress in experimental techniques to produce multiply charged ions, various heavy ions with high charge become available and the collision physics with highly-charged heavy ions is rapidly developing. Considering this fact, it is worthwhile to calculate the atomic excitation cross sections for these heavy ions by the use of relativistic wave functions.

In the present work, the relativistic calculations on the atomic excitation cross sections from the K shell to the L1, L2, and L3 shells of hydrogen-like ions by charged-particle impact have been made in the PWBA. The relativistic hydrogenic (Dirac) wave functions are used for the target electrons, while the projectile is treated nonrelativistically. The relativistic cross sections are compared with the corresponding nonrelativistic ones and the electronic relativistic effect is studied.

II. THEORY

The fundamental assumptions and general formalism of the PWBA are described in many standard texts on atomic collision theory. Here we follow the approach of McDowell and Coleman. Throughout the present work, atomic units are used and the excitation cross section is given in units of $\pi a_0^2$, where $a_0$ is the first Bohr orbit of hydrogen.

We assume that the target ion is at rest at the origin of the coordinate. The projectile is treated as a bare nucleus with nuclear charge $Z_1$ and the atomic number of the target ion is denoted by $Z_2$. We consider only single-electron excitation process. The cross section for excitation from state $i$ to state $f$ in atomic collision is written by

$$Q = \frac{\mu^2}{2\pi^2} \frac{1}{k_i^2} \int_{p_{\min}}^{p_{\max}} |T_{if}|^2 p dp,$$

where $\mu$ is the reduced mass, $k_i$ is the initial relative momentum, and $p$ is the momentum transfer. When the final momentum is expressed as $k_f$, the maximum and minimum values of $p$ are given by

$$p_{\max} = |k_i - k_f|,$$

and

$$p_{\min} = |k_i + k_f|.$$

The matrix element $T_{if}$ is written by

$$T_{if} = \langle \psi_f(R) \phi_f(r) | V(R, r) | \psi_i(R) \phi_i(r) \rangle,$$

where $R$ is the position vector of the projectile, $r$ is that of the target electron, $\psi_i$ and $\phi_f$ are the initial and final wave functions of the projectile, and $\phi_i$ and $\phi_f$ are those of the target electron. The interaction potential between the projectile and the target electron is

$$V(R, r) = Z_1 Z_2 \frac{Z_1 Z_2}{R - |R - r|}.$$

In the PWBA, the wave functions of the projectile are

$$\psi_i(R) = e^{ik_i R}, \quad \psi_f(R) = e^{ik_f R}.$$

Substitution of Eq. (4) in Eq. (2) yields

$$T_{if} = Z_1 \int dR \int dxe^{i(p - p_f)R} \frac{Z_2}{R - |R - r|} \phi_i(r).$$

The $R$ integration can be made as usual. Using the orthogonal property of the wave function, Eq. (5) reduces to

$$T_{if} = -\frac{4\pi Z_1}{\rho^2} \int e^{ipr} \phi_f^*(r) \phi_i(r) dr.$$

Inserting Eq. (6) into Eq. (1), the excitation cross section is written as

$$Q = \frac{\mu^2}{2\pi^2} \frac{1}{k_i^2} \int_{p_{\min}}^{p_{\max}} |T_{if}|^2 p dp.$$
where \( v = k_i/\mu \) is the initial velocity of the projectile and

\[
\mathcal{S}(p; i \rightarrow f) = \int e^{ipr}\phi^*_f(r)\phi_i(r)dr.
\]

The relativistic hydrogenic wave functions are given by

\[
\begin{align*}
\phi(r) &= \left( g_s(r) \chi^s(\hat{r}) \
            f_s(r) \chi^s(\hat{r}) \right),
\end{align*}
\]

where \( \kappa \) is the relativistic quantum number, \( \mu \) is the magnetic quantum number, \( \chi^s(\hat{r}) \) is the spin-angular momentum part of the wave function, and \( \hat{r} \) is the unit vector of the direction of \( r \). The large and small components of the radial wave function are

\[
\begin{align*}
g_k(r) &= N(1+W)^{1/2}(\omega_0 + \omega_1 r)r^l e^{-lr}, \\
f_k(r) &= -N(1-W)^{1/2}(\omega_0 + \omega_1 r)r^l e^{-lr},
\end{align*}
\]

The parameters, \( N, W, \omega_0, \omega_1, c_0, c_1, \gamma, \) and \( \lambda \), are defined in Ref. 8 for K, L, L2, and L3 shells.

By the use of the wave functions in Eq. (10), the relativistic matrix elements are

\[
\begin{align*}
\mathcal{S}(p; K \rightarrow L_1) &= G_0(p), \\
\mathcal{S}(p; K \rightarrow L_2) &= (4\pi)^{1/2}C_{(1/2 1 1/2; \mu_1, \mu_2 - \mu_1)}Y_{1/2}^1 \mathcal{F}_{1}(p) G_1(p), \\
\mathcal{S}(p; K \rightarrow L_3) &= (4\pi)^{1/2}C_{(1/2 3/2; \mu_2 - \mu_1)}Y_{3/2}^1 \mathcal{F}_{1}(p) G_1(p),
\end{align*}
\]

where

\[
\begin{align*}
G_L(p) &= N_1N_2[(\omega_0 W_+ + \omega_1 W_-)I_0^{(L)} + (c_1 W_+ + c_1 W_-)I_1^{(L)}], \\
W_+ &= [(1 + W_1)(1 + W_2)]^{1/2}, \\
W_- &= [(1 - W_1)(1 - W_2)]^{1/2}, \\
I_1^{(L)} &= \int_0^\infty e^{-(\gamma_1 + \lambda_1)l} j_L(pr)r^{l-1}r^{l+1}dr,
\end{align*}
\]

\( C(a, b; c; d, e) \) is the Clebsch-Gordan coefficient, \( Y_{lm}(\hat{r}) \) is the spherical harmonics, \( \hat{r} \) is the unit vector in the direction of \( p \), and \( j_L(x) \) is the spherical Bessel function of order \( L \). The parameters, \( N_1, W_1, \gamma_1, \) and \( \lambda_1 \) correspond to those for the K-shell electron, while \( N_2, W_2, \gamma_2, \lambda_2, a_0, a_1, c_0, \) and \( c_1 \) are the parameters for L\(_j\)-shell electron \((j=1-3)\).

The radial integral \( I_1^{(L)}(p) \) [Eq. (15)] is obtained analytically using the definition of the spherical Bessel function and the integration formula. The final expression is given by

\[
\int_0^\infty e^{-ax}j_\nu(bx)x^\nu dx = \left( \frac{\pi}{2b} \right)^{1/2} \frac{\beta^{l+1/2} \Gamma(l+\mu+1)}{2^{l+1/2}a^{l+\nu+1} \Gamma(l+\nu+1)} \times _2F_1\left( \frac{L+\mu+1}{2}, \frac{L+\nu+2}{2}; l+3/2; -\frac{b^2}{a^2} \right),
\]

where

\[
Q = \frac{8Z^2}{v^5} \int_{p_{\text{min}}}^{p_{\text{max}}} \frac{1}{3} |\mathcal{S}(p; i \rightarrow f)|^2 dp,
\]

\( \gamma = k_i/\mu \) is the initial velocity of the projectile and
where \( _2F_1(a, b; c; x) \) is the Gauss-type hypergeometric function.

Letting \( \gamma = |\kappa| \) for the initial and final states, Eqs. (11), (12), and (13) reduce to the corresponding nonrelativistic limits. These results are equivalent to the nonrelativistic expressions of Bates and Griffing:

\[
J(\rho; 1s\rightarrow 2s) = 2^{1/2} Z^2 \rho^3 / (9Z_e^2 + 4\rho^2)^{3/2},
\]

and

\[
J(\rho; 1s\rightarrow 2p) = 3 \cdot 2^{1/2} Z^2 \rho^3 / (9Z_e^2 + 4\rho^2)^{3/2}.
\]

III. RESULTS AND DISCUSSION

We have performed the PWBA calculations for the K—L₁, K—L₂, and K—L₃ excitation cross sections using the relativistic and nonrelativistic hydrogenic wave functions for the target electrons. The projectile is considered as a bare nucleus and the target is a hydrogen-like ion. In the nonrelativistic case, the LS-coupled wave functions are used for the L₂- and L₃-shell electrons in the target ion. All the numerical calculations in the present work have been made on the FACOM M-382 computer in the Data Processing Center of Kyoto University.

In Fig. 1, the relativistic and nonrelativistic cross sections of the K—L₁ excitation for protons on Fe²⁵⁺ ion are plotted as a function of proton energy. These results are

\[
\begin{align*}
\text{p on Fe}^{25+} & \\
\text{K—L}_1 & \\
\text{ENERGY (MeV)} & \\
0.1 & 0.5 & 1 & 5 & 10 \\
10^{-9} & 10^{-8} & 10^{-7} & 10^{-6} & 10^{-5}
\end{align*}
\]

Fig. 1. Cross sections for K—L₁ excitation of Fe²⁵⁺ ion by proton impact. The solid curve represents the relativistic cross sections and the dashed curve indicates the nonrelativistic ones.

(15)
in good agreement with the values obtained from the impact-parameter method with straight-line trajectory.\textsuperscript{5) For low energies, the relativistic cross sections are slightly larger than the nonrelativistic ones, but in the high-energy region the nonrelativistic values become larger. The relativistic PWBA cross sections of the K—L$_1$ excitation of Sn$^{49+}$ and U$^{91+}$ ions by proton impact were also calculated and found to agree well with the results of the previous work in the impact-parameter approach.\textsuperscript{5) Figure 2 shows comparison of the relativistic and nonrelativistic PWBA cross sections of the K—L$_2$ and K—L$_3$ excitation for protons on Fe$^{25+}$ ion. For these cases, the relativistic cross sections are larger than the nonrelativistic ones in low-energy region and smaller at high energies. The relativistic effect is larger for L$_3$ shell than for L$_2$ shell. The K—L$_2$ and K—L$_3$ excitation cross sections for proton impact on Sn$^{49+}$ ion are plotted in Fig. 3 as a function of proton energy. Although the relativistic effect is somewhat enhanced, the general trend of the cross sections as a function of energy is similar to that for Fe$^{25+}$ ion.
Figure 4 demonstrates the relativistic effect in the K—L₂ and K—L₃ excitation cross sections for protons on U⁹¹⁺ ion. At 1 MeV, the relativistic K—L₂ excitation cross section is approximately 7 times larger than the nonrelativistic one. With increasing energy the relativistic curve approaches to the nonrelativistic line and then becomes lower than the latter. For the energy of 100 MeV, the relativistic value is about 1.5 times smaller. The relativistic K—L₃ cross section is slightly larger than the nonrelativistic value in low-energy region and becomes smaller for the energy region above 2 MeV. At 100 MeV the former value is about one half of the latter and nearly equal to the nonrelativistic value for the K—L₂ excitation.

The K—L excitation cross sections of U⁹¹⁺ ion by ¹²C⁺⁺-ion impact are shown in Fig. 5. The energy scale is expressed as the projectile energy divided by its mass. In this case, the universal property of the cross section for projectile mass and charge does not hold because of the definition of $p_{\text{min}}$.

In conclusion, we have calculated the relativistic PWBA cross sections of hydrogen-
like ions by heavy charged-particle impact for K—L₁, K—L₂, and K—L₃ excitation. It is found that in low-energy region the relativistic effect increases the cross section, but decreases it for high-energy projectiles.

The relativistic effect can be ascribed to two reasons, the relativistic wave functions and the relativistic binding energies. The use of the relativistic wave functions increases the excitation cross section in all cases studied here. The enhancement of the cross section is large for low energies and small at high energies. On the other hand, the relativistic binding energies decrease the cross section.

In the low-energy region the enhancement due to the wave-function effect surpasses the reduction due to the use of the relativistic binding energies and the relativistic cross section is larger than the nonrelativistic one. On the contrary, the situation is reversed for high energies and the relativistic cross section becomes smaller the nonrelativistic cross section.
