#### Received June 5, 1994

Structures of series of  $TeO_2$ -WO<sub>3</sub> glasses are studied by X-ray radial distribution function (RDF) and Raman spectroscopic methods. Atomic distances around Te atoms are obtained from the experimental RDF. Structural configuration in nearest neighbor (a variety of polyhedra related to  $TeO_2$  and WO<sub>3</sub> structural components) are obtained from the Raman spectra. From the results of the RDF, Te-O (W-O) interatomic distances are in the range of 0.193–0.194 and Te-Te, 0.364–0.365 nm for 90TeO<sub>2</sub>-10WO<sub>3</sub> and  $80TeO_2$ -20WO<sub>3</sub> glasses. The Raman studies for  $80TeO_2$ -20WO<sub>3</sub>,  $75TeO_2$ -25WO<sub>3</sub> and  $70TeO_2$ -30WO<sub>3</sub> glasses indicate that there existed TeO<sub>4</sub> trigonal bipyramid, deformed TeO<sub>3+1</sub> polyhedron and TeO<sub>3</sub> trigonal pyramid associated with TeO<sub>2</sub> component. In relation to WO<sub>3</sub> component, there existed WO<sub>4</sub> tetrahedron and WO<sub>6</sub> octahedron. Structures of TeO<sub>2</sub>-WO<sub>3</sub> glasses are basically retained structural conformation found in crystalline paratellurite in spite of that there existed polyhedra of WO<sub>3</sub> component as modifier.

KEY WORDS: Glass Structure/ TeO<sub>2</sub>-WO<sub>3</sub> Glasses/ X-ray Distribution Function Analysis/ Raman Spectroscopy\*

## 1. INTRODUCTION

Hitherto, the most studies of tellurite glasses have been reported from viewpoints of glass formation<sup>1)</sup> as well as optical,<sup>2)</sup> dielectric<sup>3)</sup> properties and so on. The tellurite glasses are also interesting from structural point of view, because their local structures have possibilities to be formed by variety of coordinates states as represented by  $\text{TeO}_x$  (x: 4+2, 4+1, 4, 3+3, 3+2, 3+1 and 3) polyhedra found in crystalline states.<sup>4)</sup> In tellurite glasses,  $\text{TeO}_2$ -WO<sub>3</sub> glass should show especially complicate local structures, because of adding to structural configurations such as WO<sub>x</sub> (x: 4 and 6) polyhedra. Recently a few structural studies of  $\text{TeO}_2$ -WO<sub>3</sub> glasses are reported. They are Infra-red (IR) spectroscopic study by Dimitrov *et al.*,<sup>5)</sup> Raman spectroscopic one by Gubov *et al.*,<sup>6)</sup> neutron diffraction one by Kozhukharov *et al.*,<sup>7)</sup> and X-ray diffraction one by Nukui *et al.*,<sup>8)</sup> Dimitrov *et al.* proposed that part of the TeO<sub>2</sub> was substituted by WO<sub>4</sub> tetrahedra. Gubov *et al.* suggested that two different coordinate states of WO<sub>4</sub> and WO<sub>6</sub> were contributed to build up the glass structure. Kozhukharov *et al.* indicated the influence of WO<sub>3</sub> as the modifier on the Te-O, Te-Te and O-O interatomic distances. Nukui *et al.* indicated that local structure 90TeO<sub>2</sub>-10WO<sub>3</sub> was similar to that in paratellurite ( $\alpha$ -TeO<sub>2</sub>). However, structural conformation by the combination of TeO<sub>x</sub> and WO<sub>x</sub> polyhedra leads to complicate

## Structural Study of TeO2-WO3 Glasses by RDF and Raman Analyses

arrangements in the glass structure and has been still remained arguments.

In the present study, we tried to analyze the local structure of  $TeO_2$ -WO<sub>3</sub> glasses by combination of Raman spectroscopic and X-ray radial distribution function (RDF) analyses in order to know what kinds of the polyhedra contribute to the local structure and to know atomic arrangement concerned with such the polyhedra.

## 2. EXPERIMENTAL

The compositions and densities of  $TeO_2$ -WO<sub>3</sub> glasses, which were quenched from melt after keeping temperature at 800°C for 30 min., are listed in Table 1. The densities were measured by Archimedes method.

Table I. Composition and density of the glasses.			
Composition	$TeO_2 \ (mol\%)$	$WO_3 \pmod{8}$	Density (g/cm <sup>3</sup> )
TW1	90	10	5.68
TW2	80	20	5.93
TW3	75	25	6.06
TW4	70	30	6.18

Table 1. Composition and density of the glasses.

Samples of TW1 and TW2 were ready for X-ray measurement and TW2, TW3 and TW4, for Raman measurement. X-ray diffraction measurement was performed by using a powder diffractometer<sup>9)</sup> at the BL-4B station of Photon Factory in National Laboratory for High Energy Physics. Measurements were carried out by monochromatized X-ray with wave length of 0.075 nm. Intensity data were collected by step scanning with every 0.4° from 4° to 140° in  $2\theta$  range adopting fixed-time counting for 30 sec. Intensity of incident beam was monitored by the scattering and fluorescent X-rays from Al foil. The collected intensities were normalized with Krogh-Moe and Norman method after correcting absorption factor and Compton scattering.

The Raman spectra of the glasses were taken in the range of  $200-1,200 \text{ cm}^{-1}$  with a SPEX RAMALOG9 type spectrometer equipped with an argon ionized laser with 514.5 nm.

## 3. RESULT

## 3.1 RDF study

Figure 1 shows intensity curves of the  $90\text{TeO}_2$ - $10\text{WO}_3$  and  $80\text{TeO}_2$ - $20\text{WO}_3$  glasses. Figure 2 shows the RDF, D(r)'s obtained as the Fourier transform of interference function deduced from the observed intensities. Main peaks located below 0.5 nm are found at 0.193–0.194 nm and 0.374–0.375 nm, and several shoulders in the range of 0.4–0.5 nm for two glasses. The interatomic distances of Te-O including a slight W-O ones, and Te-Te (W-W) in the TeO<sub>2</sub>-WO<sub>3</sub> glasses together with those of crystalline  $\alpha$ -TeO<sub>2</sub> and Li<sub>2</sub>TeO<sub>3</sub> are listed in Table 2.

## 3.2 Raman Study

Raman spectra of the tellurite glasses with composition of 20, 25 and 30mol% WO<sub>3</sub> contents are shown in Figure 3. In the spectra of the glasses, three bands (around 500, 700 and 930 cm<sup>-1</sup>) and several shoulders (around 350, 800 and  $850 \text{ cm}^{-1}$ ) are found. The bands below 800–900 cm<sup>-1</sup> should be mainly contributed by TeO<sub>2</sub> component as refering to Sekiya's Raman

study of a various kind of tellurite glasses.<sup>10)</sup> Comparing these spectra with those of the other tellurite glasses with different modifiers such as  $TeO_2-R_xO_y$  (ex. R: alkali earth elements and so on),<sup>10)</sup> the sharp band beyond the 900 cm<sup>-1</sup>, relatively large shoulder around 350 cm<sup>-1</sup> and small one around 850 cm<sup>-1</sup> are observed additionally. Those correspond to contribution of WO<sub>3</sub> component. Gubov *et al.* proposed that the band at about 930 cm<sup>-1</sup> was contributed by WO<sub>4</sub> tetrahedron, because B<sub>2</sub>WO<sub>4</sub> crystal, which consisted of WO<sub>4</sub> tetrahedra, showed such the band at 930 cm<sup>-1</sup>. While Daniel *et al.*<sup>11)</sup> observed the band in Raman spectra related to tungsten oxide (*m* and *h*-WO<sub>3</sub>), which consisted of WO<sub>6</sub> octahedra with corner sharing,

	Te-O (nm)	Te-Te (nm)
90TeO <sub>2</sub> -10WO <sub>3</sub>	0.194*1	0.364*2
80TeO <sub>2</sub> -20WO <sub>3</sub>	0.193*1	0.365 <sup>*2</sup>
$\alpha$ -TeO <sub>2</sub>	0.191	0.374
	0.208	
$Li_2TeO_3$	0.185	0.385

did not show the band at about  $930 \,\mathrm{cm}^{-1}$ .

The Raman spectra obtained in the present study were deconvoruted by adopting Gaussian functions distributed at the corresponding band positions to those of TeO4 trigonal bipyramid, deformed TeO3+1 polyhedron and TeO3 trigonal pyramid in TeO2 component according to Mochida et al. and those of WO<sub>4</sub> tetrahedron and WO<sub>6</sub> octahedron in WO<sub>3</sub> component.<sup>6)</sup> As the results, the total spectra could be assighted by bands at 780, 650 and  $480 \text{ cm}^{-1}$  which are

## A. NUKUI, Y. SHIMIZUGAWA, S. SUEHARA, S. INOUE and T. MAESETO

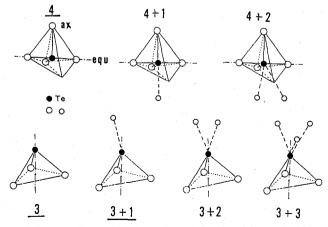

belong to TeO<sub>2</sub> component and by bands at 940, 870 and  $380 \text{ cm}^{-1}$  for WO<sub>3</sub> component. Furthermore, the band at 780 cm<sup>-1</sup> is belong to TO<sub>3</sub> polyhedron. That at 720 cm<sup>-1</sup> is belong to TeO<sub>3+1</sub> polyhedron, and 650 and 480 cm<sup>-1</sup>, to TeO<sub>4</sub> polyhedron, respectively. On the other hand, the band at 940 cm<sup>-1</sup> corresponds to WO<sub>4</sub> tetrahedron, and 870 and 380 cm<sup>-1</sup>, to WO<sub>6</sub> octahedron, respectively.

## 4. **DISCUSSION**

The possible configurations of the polyhedra of  $TeO_2$  component are shown in Figure 4. The Raman analysis indicates the coexistence of a various kinds of primary polyhedra such as  $TeO_4$  trigonal bipyramid ( $TeO_4$  tbp), deformed  $TeO_{3+1}$  polyhedron and  $TeO_3$  trigonal pyramid ( $TeO_3$  tp) for  $TeO_2$  component, and WO<sub>4</sub> octahedron and WO<sub>6</sub> octahedron for WO<sub>3</sub> one. While interatomic distance related to the neighbor environment around Te atom such as Te-O and that of Te-Te with slight contribution of W-O and W-W atomic pairs, respectively are obtained by the RDF analysis.

The structures of tellurite glasses are usually explained on the basis of structural units of paratellurite ( $\alpha$ -TeO<sub>2</sub>) and of the tellurite compounds which have similar compositions to glasses. The structure of  $\alpha$ -TeO<sub>2</sub> consists of structure unit which Te atom is surrounded by four oxygen atoms. Two oxygen atoms situated at 0.191 nm in equatorial plane. The other two situated at 0.208 nm in axial plane. While structure of m-WO<sub>3</sub> crystal consists of WO<sub>6</sub> octahedra in which the W atoms are off-center, and form three short (0.18 nm) and three long (0.21 nm) W-O bonds with the surrounding oxygens. The theoretical value of Te-O in TeO<sub>2</sub> glass<sup>6)</sup> and the average one in  $\alpha$ -TeO<sub>2</sub> are 0.20 nm, respectively. While W-O interatomic distance in the glass is 0.188 nm.<sup>6)</sup>

The first peaks found in the RDF for  $90\text{TeO}_2$ -10WO<sub>3</sub> and  $80\text{TeO}_2$ -20WO<sub>3</sub> are corresponded to Te-O interatomic distances with a small amount of contribution of W-O atomic pairs and located at 0.194 and 0.193 nm, respectively. It is reasonable to show such the values, because of overlapping of Te-O atom pair (0.20 nm) and W-O one with shorter interatomic distance (0.188 nm). The Te-O interatomic distance become short slightly with increasing of WO<sub>3</sub> contents

#### Structural Study of TeO2-WO3 Glasses by RDF and Raman Analyses

from 10 to 20 mol%. This tendency may correspond to configuration change from TeO<sub>4</sub>tbp to deformed TeO<sub>3+1</sub> polyhedra.

The important thing is the difference of the shortest Te-Te distances as well as the firstneighbor Te-O distance. In the results of neutron diffraction by Kuzhukharov et al., they insisted that the peak at 0.38–0.39 nm was strongly diffusive, because this region of atomic arrangement in the glass was affected by the strong deformation of the bonds contributing to the RDF. On the other hand, the results of X-ray diffraction study by Nukui et al. and the other tellurite glasses<sup>12</sup>) with different elements of compositions indicate that the peak at that region (around 0.37 nm) is extremely large and relatively sharp. There is large difference between the results of neutron and X-ray works. In the neutron experiment, the scattering factor to Te, W and O are almost same to each other. While local structures of TeO2-WO3 glasses have retained as a whole, three dimential network found in  $\alpha$ -TeO<sub>2</sub> from viewpoint of atomic distance of Te-O and Te-Te atom pairs in spite of that the local structure has a variety of polyhedra of TeO<sub>2</sub> and WO<sub>3</sub> components. Therefore, taking into account of the facts described above, the diffuse like shoulder in RDF by the neuron diffraction measurement indicates that "smearing" do not deduce from strong deformation of atomic arrangement in the region (around 0.38 nm) but averaging of the contributions of Te-Te, W-W, the second neighbor Te-O and W-O, and O-O atom pairs, although the tendency of deformation shows to some extent as the results of adding to WO<sub>3</sub> component as modifier or even as networkformer.

Dimitrov *et al.* assumed that the WO<sub>4</sub>-tetrahedra a part of TeO<sub>4</sub> groups was replaced by WO<sub>4</sub> tetrahedra, which leads to the formation of Te-O-W-O-Te bonds in the structure, by IR spectroscopic study. With increase in the WO<sub>3</sub> content, WO<sub>4</sub> tetrahedra as well as TeO<sub>3+1</sub> and TeO<sub>3</sub> polyhedra increase as can be seen in Figure 3. This fact indicate that elongated Te-O bond has possibility to combine to WO<sub>4</sub> tetrahedron or WO<sub>5</sub> octahedra.

The structural conformation by combination of  $\text{TeO}_x$  and  $WO_x$  polyhedra leads to complicate atomic arrangements through the glass structure. A further study will be performed by partial RDF employing X-ray anomalous scattering in order to make clear the atomic arrangements through the glass structure.

## 5. CONCLUSION

Structures of series of TeO<sub>2</sub>-WO<sub>3</sub> glasses are studied by RDF and Raman spectroscopic methods. Atomic distances around Te atoms are obtained from the RDF. Structural configuration in the nearest neighbor are obtained from the Raman spectra. The Raman studies of series of TeO<sub>2</sub>-WO<sub>3</sub> glasses indicate that there existed TeO<sub>4</sub> trigonal bipyramid, deformed TeO<sub>3+1</sub> polyhedron and TeO<sub>3</sub> trigonal pyramid associated with TeO<sub>2</sub> component. In relation to WO<sub>3</sub> component, there existed WO<sub>4</sub> tetrahedra and WO<sub>6</sub> octahedra. With increase in the WO<sub>3</sub> content, WO<sub>4</sub> tetrahedra as well as TeO<sub>3+1</sub> and TeO<sub>3</sub> polyhedra increase. Structures of TeO<sub>2</sub>-WO<sub>3</sub> glasses are basically retained structural conformation found in crystalline paratellurite in spite of that there existed distinctive polyhedra of WO<sub>3</sub> component.
