1 Introduction

This is a brief report on the results in [1].

Let us consider two electrons coupled with longitudinal optical (LO) phonons in a 3-dimensional crystal now. Then, in general, an electron is dressed in a phonon cloud because of the electron-phonon interaction. The dressed electron is the so-called polaron [2, 3]. If the Coulomb repulsion between the two electrons is strong enough, the two electrons are so far away from each other that each electron dresses itself in an individual phonon cloud. Thus, there is no exchange of phonons between the two. On the other hand, if the distance between the two electrons is so short that a common phonon cloud grasps both electrons, then the phonon-exchange takes place. In this case, there is a possibility that attraction appears between them and thus we can expect that they are bound to each other. The bound two polarons is called a bipolaron [4, 5, 6, 7, 8, 9]. We consider the tug of war between the two electrons.

The total Hamiltonian $H_{BP}$ of bipolaron we consider is given by

$$H_{BP} = H_{el-el} + H_{ph} + H_{el-ph}.$$  \hspace{1cm} (1.1)

where

$$H_{el-el} = \sum_{j=1,2} \frac{1}{2m} p_j^2 + \frac{U}{|x_1 - x_2|},$$  \hspace{1cm} (1.2)

$$H_{ph} = \sum_k \hbar \omega_k a_k^\dagger a_k,$$  \hspace{1cm} (1.3)

$$H_{el-ph} = \sum_{j=1,2} \sum_k \left\{ V_k e^{ik \cdot x_j} a_k + V_k^* e^{-ik \cdot x_j} a_k^\dagger \right\}.$$  \hspace{1cm} (1.4)

In Eq.(1.2), $x_j$ and $p_j$ denote the position and momentum operators of the $j$th electron ($j = 1, 2$) of mass $m$, respectively, so $p_j = -i\hbar \nabla x_j$. The symbol $U$ stands for the strength of the Coulomb repulsion, so $U \equiv e^2/\epsilon_{\infty}$ for the electric
charge $e$ and the optic dielectric constant $\epsilon_{\infty}$. In Eq.(1.3), $a_k$ and $a_k^\dagger$ are the annihilation and creation operators, respectively, of the LO phonon with the momentum $\hbar k$. Since phonons are bosons, $a_k$ and $a_k^\dagger$ satisfy the canonical commutation relation. We can set the dispersion relation $\omega_k$ as $\omega_k = \omega_{LO}$ because the LO phonons can be assumed to be dispersionless. In Eq.(1.4), $V_k$ is defined by $V_k := -i\hbar \omega_{LO} (4\pi \alpha r_{fp}/k^2 V)^{1/2}$ for the crystal volume $V$ and the free polaron radius $r_{fp} \equiv (\hbar/2m\omega_{LO})^{1/2}$. The dimensionless electron-phonon coupling constant is

$$\alpha := \frac{1}{\hbar \omega_{LO}} \frac{\epsilon^2}{2} \left( \frac{1}{\epsilon_{\infty}} - \frac{1}{\epsilon_0} \right) \frac{1}{r_{fp}},$$

(1.5)

where $\epsilon_0$ is the static dielectric constant. We define the ionicity $\eta$ of the crystal by $\eta := \epsilon_{\infty}/\epsilon_0$. so $0 < \eta < 1$. Then, the strength of the Coulomb repulsion is rewritten as $U = \sqrt{2}\alpha/(1-\eta)$. We note the wave vector $k$ in $\sum_k$ runs over the first Brillouin zone because we consider the two-body system of large polarons.

From now on, we use the natural units $\hbar = m = \omega_{LO} = 1$ in this report. Using the well-known conversion of sums to integrals, we estimate $\sum_k |V_k|^2$ at $\sqrt{2}\alpha K/\pi$, where $K$ means the radius of a sphere of the first Brillouin zone. Using the approximation of the Fourier expansion, $V/(4\pi|x|) \approx \sum_k e^{ik \cdot x}/k^2$, we have

$$\sum_k |V_k|^2 e^{ik \cdot x} \approx \frac{\alpha}{\sqrt{2}|x|}.$$

(1.6)

We often use this approximation (1.6).

In this report we say $H_{BP}$ has a ground state if $H_{BP}$ has an eigenvector of which eigenenergy is the lowest point spectrum of $H_{BP}$. We note $H_{BP}$ has translation invariance. Thus, to give a possibility that $H_{BP}$ has a ground state, we put a device in the interaction Hamiltonian:

$$H_{el-ph}(\rho) = \rho(x_1 + x_2) \sum_{j=1,2} \sum_k \left\{ V_k e^{ik \cdot x_j} a_k + V_k^* e^{-ik \cdot x_j} a_k^\dagger \right\},$$

where $\rho(x)$ is a function satisfying $0 \leq \rho(x) \leq 1$. We employ $H_{el-ph}(\rho)$ in $H_{BP}$ instead of $H_{el-ph}$:

$$H_{BP} = H_{el-el} + H_{ph} + H_{el-ph}(\rho).$$

For instance, we define $\rho(x)$ so that $\rho(x) = 0$ outside the crystal and $\rho(x) = 1$ inside the crystal. We can also define $\rho(x)$ by $\rho(x) \equiv \rho_Q(x)$, where $\rho_Q(x) := 1$ if $x = 2Q$; $\rho_Q(x) := 0$ if $x \neq 2Q$. For $\rho(x) \equiv 1$ the Hamiltonian $H_{el-el} + H_{ph} + H_{el-ph}(\rho)$ becomes the original $H_{BP}$. 
2 Spatial Localization in Weak-Coupling Regime

We define a positive constant $E_w(\alpha)$ by
\[ E_w(\alpha) := 4 \sum_k |V_k|^2 = \frac{4\sqrt{2} \alpha}{\pi} K = \frac{8\sqrt{2} \alpha c}{\Lambda} \] (2.1)
for every $\alpha > 0$, where $\Lambda$ is a wave length defined by $\Lambda := 2\pi/K$.

When $H_{BP}$ has a ground state $\Psi_0$, we define the distance $d_{BP}(\Psi_0)$ between the two electrons in bipolaron by
\[ d_{BP}(\Psi_0) := \langle \Psi_0 | \Psi_0 \rangle^{-1} \langle \Psi_0 | x_1 - x_2 | \Psi_0 \rangle. \] (2.2)
We say that the relative motion of the bipolaron in a bound state $\Psi_n$ is spatially localized in the closed ball $\overline{B}(r)$ if $d_{BP}(\Psi_0) \leq r$.

Using and developing Lieb’s idea [10], we can show that the relative motion of the bipolaron in a ground state is not spatially localized in $\overline{B}(r)$, provided that the ground state exists under the condition:
\[ E_w(\alpha) < \frac{U}{r} \quad \text{(i.e., } 0 \leq 1 - \frac{\Lambda}{8r} < \eta \text{)}. \] (2.3)

3 Bipolaron Formation

We consider the original $H_{BP}$ (i.e., in the case $\rho(x) \equiv 1$) in the strong-coupling regime in this section. We derive two effective Hamiltonians from $H_{BP}$ by modifying Bogolubov's method [11], which is similar to Adamowski’s [5] and ours [12].

We find a canonical transformation $U_\theta$ with the parameter $\theta \geq 0$ so that $H_{BP}(\theta) := U_\theta^* H_{BP} U_\theta = H_{eff}(\theta) + H_{ph} + H_{el-ph}(\theta) + \Sigma_\theta$, where $H_{eff}(\theta)$ is an effective Hamiltonian in quantum mechanics, and $\Sigma_\theta$ a divergent energy as $\theta \rightarrow \infty$. Then, we make the effective Hamiltonian $H_{eff}(\theta)$ should have an attractive potential $V(\theta)$ from the phonon field as $H_{eff}(\theta) = H_{el-el} + V(\theta)$. By the help of this extra attractive potential $V(\theta)$, we expect a critical point $\theta_c$ so that the Hamiltonian $H_{eff}(\theta)$ itself or the Hamiltonian $H_{eff}^{rel}(\theta)$ for the relative motion of $H_{eff}(\theta)$ has a ground state if $\theta > \theta_c$. On the other hand, it has no ground state if $\theta < \theta_c$.

We can show that the approximation (1.6) yields an effective Hamiltonian describing balanced state [1] in quantum mechanics:
\[ H_{eff}(\theta) = H_{el-el} + V(\theta) = \frac{1}{2} p_1^2 + \frac{1}{2} p_2^2 + \frac{U(\theta)}{|x_1 - x_2|} \] (3.1)
with
\[
U(\theta) = U - \sqrt{2} \alpha \theta = \sqrt{2} \alpha \left( \frac{1}{1 - \eta} - \theta \right).
\] (3.2)

Clearly \( \theta_c = 1/(1 - \eta) \).

Let \( c_* \) be an arbitrary constant so that \( 0 < c_* < 1 \). We set \( c_{BP} \) as:
\[
c_{BP} := \frac{2}{5} \left( c_* - \frac{1}{\theta(1 - \eta)} \right)^2.
\] (3.3)

Then, the effective Hamiltonian \( H_{\text{eff}}(\theta) \) in Eq.(3.1) leads us to an upper bound to \( E_{BP} \) as:
\[
E_{BP} \leq - c_{BP} \alpha^2 \theta^2 + \frac{\sqrt{2} \alpha \theta}{\pi} \left( 4K + \frac{K^3}{3} \right),
\] (3.4)

provided that
\[
1 - \frac{1}{c_* \theta} > \eta.
\] (3.5)

We note that the condition (3.5) prohibits us from taking the limit \( \theta \to 0 \) in the inequality (3.4) because
\[
\theta > \frac{1}{c_* (1 - \eta)} = \frac{1}{1 - \eta}.
\]

We can also show that a lower bound to \( E_{BP} \) as:
\[
E_{BP} \geq \left( \inf_{\varphi} \mathcal{E}_{\theta}(\varphi) \right) \alpha^2 \theta^2 - \left| 1 - \frac{1}{\theta} \right| \frac{4 \sqrt{2} \alpha \theta}{\pi} K.
\] (3.6)

where
\[
\mathcal{E}_{\theta}(\varphi) := \frac{1}{2} \int \int d^3x_1 d^3x_2 \left[ |\nabla x_1 \varphi(x_1, x_2)|^2 + |\nabla x_2 \varphi(x_1, x_2)|^2 + \frac{2 \sqrt{2}}{\theta(1 - \eta)} \left| \varphi(x_1, x_2) \right|^2 \right]
\]
\[
- \frac{1}{\sqrt{2}} \int \int d^3x_1 d^3x_2 \int \int d^3y_1 d^3y_2 \sum_{j,j'=1.2} \frac{|\varphi(x_1, x_2)|^2 |\varphi(y_1, y_2)|^2}{|x_j - y_{j'}|}
\] (3.7)

is an energy functional describing unbalanced state [1] and \( \inf_{\varphi} \mathcal{E}_{\theta}(\varphi) < 0 \).

We can obtain another effective Hamiltonian. The approximation (1.6) yields another effective Hamiltonian describing unbalanced state [1] in quantum mechanics:
\[
H_{\text{eff}}(\theta) = \alpha^2 \theta^2 \left[ \sum_{j=1.2} \frac{1}{2} p_j^2 - \sqrt{2} \sum_{j=1.2} \frac{1}{|x_j|} + \frac{\sqrt{2}}{\theta(1 - \eta)|x_1 - x_2|} \right].
\] (3.8)
Then, the transformed total Hamiltonian $H_{\text{BP}}[\theta]$ is approximated as:

\[
H_{\text{BP}}[\theta] \approx H_{\text{eff}}(\theta) + H_{\text{ph}} + \sum_{j=1,2} \sum_{k} \left\{ V_k \left( e^{ik \cdot x_j / \alpha \theta} - \theta \right) a_k + V_k^* \left( e^{-ik \cdot x_j / \alpha \theta} - \theta \right) a_k^\dagger \right\} + \Sigma_\theta.
\]

\[(3.9)\]

where $H_{\text{eff}}(\theta)$ is given by Eq.(3.8) and $\Sigma_\theta := \theta E_w(\alpha)/4$. Here the approximation (1.6) breaks the translation invariance in the original Hamiltonian $H_{\text{BP}}$.

Let $E_s(\alpha)$ be

\[
E_s(\alpha) := \left( \frac{2\sqrt{2}}{r} - \frac{1}{r^2} - 1 \right) \alpha \theta
\]

\[(3.10)\]

now. Then, the effective Hamiltonian $H_{\text{eff}}(\theta)$ in Eq.(3.8) has a ground state if there is an $r > 0$ so that

\[
\frac{U}{r} < E_s(\alpha).
\]

\[(3.11)\]

Then, we have $\theta_c \leq 1/(2 - \sqrt{2})(1 - \eta)$. The condition (3.11) puts restrictions on $\theta, \eta$ and $r$. The sufficient condition for the inequality (3.11) is:

\[
1 - \frac{1 + \sqrt{2}}{\sqrt{2} \theta} > \eta.
\]

\[(3.12)\]

and

\[
R_{\theta,\eta} - \sqrt{R_{\theta,\eta}^2 - 1} < r < R_{\theta,\eta} + \sqrt{R_{\theta,\eta}^2 - 1}.
\]

\[(3.13)\]

where

\[
R_{\theta,\eta} := \sqrt{2} \left( 1 - \frac{1}{2\theta(1 - \eta)} \right).
\]

(i.e., $\theta \approx \infty$), $0.585 \leq r/r_{fp} \leq 3.415$.

4 Spatial Localization in Strong-Coupling Regime

In this section we deal with the approximated $H_{\text{BP}}[\theta]$ given in Eq.(3.9). When a ground state $\Psi_0$ of $H_{\text{BP}}[\theta]$ exists, we define the radius $u_{\text{BP}}(\Psi_0)$ of the sphere in which the two electron lives by

\[
u_{\text{BP}}(\Psi_0) := \max_{j=1,2} \left\{ \langle \Psi_0 | \Psi_0 \rangle^{-1} \langle \Psi_0 | x_j | \Psi_0 \rangle \right\}.
\]

\[(4.1)\]
Then, we can show that if the bipolaron has a ground state $\Psi_0$, then there is a relation:

$$u_{BP}(\Psi_0) \geq \frac{1}{\sqrt{2}} \left( 1 + \left( 1 + \frac{3\theta}{4} \right) \frac{E_w(\alpha)}{\alpha^2} \right)^{-1} \left( \frac{1}{\theta(1-\eta)} - 2 \right).$$ (4.2)

Thus, even if $\eta$ approaches 1, $\theta > 0$ in the strong-coupling regime works to prevent its size from growing. This is a noticeable difference from the case of the weak-coupling regime.

5 Positive Binding Energy

We obtain a sufficient condition for the binding energy being positive. Let $E_{P}(\psi)$ be the Pekar functional [13, 14, 15, 16, 17] for single polaron, i.e.,

$$E_{P}(\psi) := \frac{1}{2} \int d^3x |\nabla_x \psi(x)|^2 - \frac{1}{\sqrt{2}} \int \int d^3x d^3y \frac{\psi(x)^2 \psi(y)^2}{|x-y|}.$$

Lieb [15] proved that there is a unique and smooth minimizing $\psi(x)$ in $c_{sp} := -\inf_{\psi \ll 1} E_{P}(\psi)$ up to translations. Then, according to the estimate of $c_{sp}$ by Miyake [14] and by Gerlach and Löwen [17],

$$c_{sp} = 0.108513 \cdots.$$

Then, if $c_{*}, \theta$, and $\eta$ satisfy $c_{BP} > 2c_{sp}$, then the binding energy is positive. i.e.,

$$E_{BP} < 2E_{sp}$$ (5.1)

for sufficiently large $\theta > 0$ with the condition (3.5). Thus, we note that $0 < c_{BP} \leq 0.4$ and $\lim_{c_{*} \rightarrow 1, \theta \rightarrow \infty} = 0.4$ under the condition (3.5).

According to the recent result of study [18], we might be able to choose $\inf_{\varphi, \ll 1} E_{\theta}(\varphi)$ as $c_{BP}$ (i.e., $c_{BP} = \inf_{\varphi} E_{\theta}(\varphi)$) so that $2E_{sp} - E_{BP} = -(2c_{sp} - c_{BP})\alpha^2 > 0$ for sufficiently large $\theta > 0$, where $E_{sp}$ is the ground state energy of the single polaron [19].
