1 Introduction

Let $\Omega$ be a bounded domain in $\mathbb{R}^d (d = 2, 3)$ and $T$ be a positive constant. We consider the problem governed by the nonstationary Navier-Stokes equations subject to the Dirichlet boundary conditions; find $(u, p): \Omega \times (0, T) \rightarrow \mathbb{R}^d \times \mathbb{R}$ such that

$$
\frac{\partial u}{\partial t} + (u \cdot \nabla) u - \nabla (2\nu D(u)) + \nabla p = f \quad \text{in } \Omega \times (0, T), \\
\nabla \cdot u = 0 \quad \text{in } \Omega \times (0, T), \\
u = g \quad \text{on } \Gamma \times (0, T), \\
u = u^0 \quad \text{in } \Omega, \text{ at } t = 0,
$$

where $u$ is the velocity, $p$ is the pressure, $f$ is an exterior force, $g$ is a boundary velocity, $u^0$ is an initial velocity, $\nu(>0)$ is a viscosity, $\Gamma \equiv \partial \Omega$, and $D(u)$ is the strain-rate tensor defined by

$$D_{ij}(u) \equiv \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right).$$

A second-order-in-time characteristic finite element scheme for convection-diffusion problems had been developed in [2], where they had proved stability and convergence theorems. Using their idea, we have developed a second order characteristic finite element scheme [1] for (1). Our scheme is the combination of a second-order-in-time characteristic finite element scheme and the first-order-in-time characteristic finite element scheme (see Figure 1). The scheme has such advantages that it is of second order in $\Delta t$ and that the matrices are symmetric. The combined scheme is stable even for high Reynolds number problems. In this paper we consider the stability. The contents of the paper are as follows.

*E-mail: notsu@math.kyushu-u.ac.jp
†E-mail: tabata@math.kyushu-u.ac.jp
... → \( (u_{h}^{n-1}, p_{h}^{n-1}) \)  
Second order  
\( \Delta t_0 = O(\Delta t) \)  
\( (u_{h}^{\alpha}, p_{h}^{\alpha}) \)  
First order  
\( \Delta t_1 = O(\Delta t^2) \)  
\( (u_{h}^{n}, p_{h}^{n}) \)  
... 

Figure 1: Time evolution of the scheme

We introduce the scheme in Section 2 and present a sufficient condition for the scheme to be stable in Section 3. In the last section we check the condition numerically in an example and solve a cavity flow problem with high Reynolds numbers.

We use the function spaces \( L^2(\Omega) \) and \( W^{1,\infty}(\Omega) \). For any normed space \( X \) we use the notation \( \| \cdot \|_X \) to represent the \( X \)-norm. We omit \( \Omega \) in the notations of norms, and use \( \| \cdot \| \) to show the \( L^2 \)-norms \( \| \cdot \|_{L^2}, \| \cdot \|_{(L^2)^d}, \| \cdot \|_{(L^2)^{d\times d}} \).

2 A second order characteristic finite element scheme

For time increments \( \Delta t, \Delta t' \) and velocities \( u, v : \Omega \to \mathbb{R}^d \), we define \( X_1(u, \Delta t) \) and \( X_2(u, v, \Delta t', \Delta t) \) by

\[
X_1(u, \Delta t)(x) \equiv x - u(x)\Delta t,
\]

\[
X_2(u, v, \Delta t', \Delta t)(x) \equiv x - \left\{ (1 + \frac{\Delta t'}{2\Delta t})u(x - u(x)\Delta t') - \frac{\Delta t'}{2\Delta t}v(x - u(x)(\Delta t' + \Delta t)) \right\} \Delta t',
\]

respectively. The \( X_i \) \((i = 1, 2)\) are used for the \( i \)-th order approximate values of upwind points. For a function \( \psi \) over \( \Omega \times (0, T) \), we set \( \psi^n \equiv \psi(\cdot, t^n) \), where \( t^n \) is defined by \( t^n \equiv n\Delta t \). The symbol \( \circ \) means the composition of functions,

\[
(\psi^n \circ X)(x) \equiv \psi^n(X(x)).
\]

Let \( T_h = \{ K \} \) be a triangulation of \( \Omega \). We define \( \Omega_h \) by

\[
\Omega_h \equiv \text{int} \bigcup \{ K : K \in T_h \}
\]

and \( \Gamma_h \equiv \partial \Omega_h \). Let \( \Delta t \) be a time increment, and \( N_0 \) be a positive integer. We set \( \alpha \equiv 1/N_0 \), \( \Delta t_0 \equiv (1 - \alpha)\Delta t \) and \( \Delta t_1 \equiv \alpha\Delta t \). We define \( \Lambda \) by

\[
\Lambda \equiv \{ n \in \mathbb{R}; n = ma, \ m \in \mathbb{N}, \ 1 \leq m \leq N_0 \} \cup \{ n \in \mathbb{R}; n \in \mathbb{N} \cup (\mathbb{N} - \alpha), \ 1 \leq n \leq N_T \}
\]

and set \( \Lambda_0 \equiv \Lambda \cup \{ 0 \} \), where \( N_T \equiv \lfloor T/\Delta t \rfloor \). In the following definitions we use the same notation \( \langle \cdot, \cdot \rangle \) to represent the \( L^2(\Omega_h) \)-inner products in the scalar- and vector-valued function spaces. Suppose \( \{ u^n_h \}_{n \in \Lambda_0} \subset H^1(\Omega_h)^d, \{ p^n_h \}_{n \in \Lambda} \subset H^1(\Omega_h) \) and \( f \in C^0(L^2(\Omega_h)^d) \) be given. We define linear forms \( A_{0h}^{\alpha}(u_h, p_h), A_{1h}^n(u_h, p_h), F_{0h}^n(f, u_h), F_{1h}^n f \) on \( H_0^1(\Omega_h)^d \) and \( B^*_{h} u_h \) on \( L^2(\Omega_h) \) as follows:

\[
\langle A_{0h}^{\alpha}(u_h, p_h), v_h \rangle \equiv \left( \frac{u_n^{\alpha} - u_{n-1}^{\alpha}}{\Delta t_0} \circ X_2(u_{n-1}^{\alpha}, u_{n-2}^{\alpha}, \Delta t_0, \Delta t), v_h \right)
\]

\[
+ \nu \left( D(u_{n-1}^{\alpha}) + D(u_n^{\alpha}) \circ X_1(u_{n-1}^{\alpha}, \Delta t_0), D(v_h) \right) + \nu \Delta t_0 \sum_{i,j,k=1}^d \left( D_{ij}(u_{n-1}^{\alpha})u_{n-1}^{(i)j}, v_{hi,k} \right)
\]

\[- \frac{1}{2} \left\{ (\nabla \cdot v_h, p_n^{\alpha}) - (\nabla p_n^{\alpha} \circ X_1(u_{n-1}^{\alpha}, \Delta t_0), v_h) \right\},
\]

where \( \Delta t_0 \equiv (1 - \alpha)\Delta t \) and \( \Delta t_1 \equiv \alpha\Delta t \).

\[\]
\[ \langle \mathcal{A}_{1h}^{n}(u_{h}, p_{h}), v_{h} \rangle \equiv \left( \frac{u_{h}^{n} - u_{h}^{n-\alpha} \circ X_{1}(u_{h}^{n-\alpha}, \Delta t_{1})}{\Delta t_{1}}, v_{h} \right) + 2\nu \left( D(u_{h}^{n}), D(v_{h}) \right) - \left( \nabla \cdot v_{h}, p_{h}^{n} \right) \]

\[ \langle \mathcal{F}_{0h}^{n-\alpha}(f, u_{h}), v_{h} \rangle \equiv \frac{1}{2} \left( f^{n-\alpha} + f^{n-1} \circ X_{1}(u_{h}^{n-1}, \Delta t_{0}), v_{h} \right) \]

\[ \langle F_{1h}^{t}f, v_{h} \rangle \equiv (f^{n}, v_{h}) \]

\[ \langle \mathcal{B}_{h}^{n}u_{h}, q_{h} \rangle \equiv (\nabla \cdot u_{h}^{n}, q_{h}) \]

We set finite element spaces

\[ X_{h} \equiv \{ v_{h} \in C^{0}(\overline{\Omega}_{h})^{d}; v_{h}|_{K} \in P_{2}(K)^{d}, \forall_{K} \} \]

\[ V_{h}(g) \equiv \{ v_{h} \in X_{h}; v_{h}(P) = g(P) (\text{node } P \in \Gamma_{h}) \} \]

\[ V_{h} \equiv V_{h}(0) \]

\[ Q_{h} \equiv \{ q_{h} \in C^{0}(\overline{\Omega}_{h}); q_{h}|_{K} \in P_{1}(K), \forall_{K}, \int_{\Omega_{h}} q_{h} \, dx = 0 \} \]

For the given function \( f \) the notation \( f_{h}(\cdot, t) \) means \( \Pi_{h}f(\cdot, t) \), where \( \Pi_{h} : C^{0}(\overline{\Omega}_{h})^{d} \rightarrow X_{h} \) is the interpolation operator.

A second order characteristic finite element approximation to problem (1) is the following; find \( \{(u_{h}^{n}, p_{h}^{n}) \in V_{h}(g^{n}) \times Q_{h}; n \in \Lambda\} \) such that

**general stage:**

\[
\begin{align*}
\mathcal{A}_{0h}^{n-\alpha}(u_{h}, p_{h}) &= \mathcal{F}_{0h}^{n-\alpha}(f_{h}, u_{h}) \quad \text{in } V_{h}', \\
B_{h}^{n-\alpha}u_{h} &= 0 \quad \text{in } Q_{h}', \\
\mathcal{A}_{1h}^{n}(u_{h}, p_{h}) &= F_{1h}^{n}f_{h} \quad \text{in } V_{h}', \\
B_{h}^{n}u_{h} &= 0 \quad \text{in } Q_{h}', \\
(n &= 2, \ldots, N_{T}),
\end{align*}
\]

**initial stage:**

\[
\begin{align*}
\mathcal{A}_{1h}^{m\alpha}(u_{h}, p_{h}) &= F_{1h}^{m\alpha}f_{h} \quad \text{in } V_{h}', \\
B_{h}^{m\alpha}u_{h} &= 0 \quad \text{in } Q_{h}', \\
u_{h}^{0} &= \Pi_{h}u^{0}, \\
(m &= 1, \ldots, N_{0}).
\end{align*}
\]

We find \( (u_{h}^{n-\alpha}, p_{h}^{n-\alpha}) \) from (2a) and find \( (u_{h}^{n}, p_{h}^{n}) \) from (2b). The absence of \( (u_{h}^{1}, p_{h}^{1}) \) is covered by (2c). (2a) is a second order scheme in \( \Delta t_{0} \), and (2b) and (2c) are first order schemes in \( \Delta t_{1} \). If we set \( \Delta t_{0} = O(\Delta t) \) and \( \Delta t_{1} = O(\Delta t^{2}) \), the scheme (2) is of second order in \( \Delta t \).

### 3 Stability of the scheme

In this section we present a proposition on the stability of the scheme. Those hypotheses are checked numerically in Section 4.

For a given series \( \{w^{n}\}_{n \in \Lambda_{0}} \) in a normed space \( X \), we introduce norms \( \| \cdot \|_{l^{\infty}(X)}, \| \cdot \|_{l^{2}(X)}, \| \cdot \|_{l^{0}(X)} \) defined by

\[
\|w\|_{l^{\infty}(X)} \equiv \max_{n \in \Lambda_{0}} \|w^{n}\|_{X}, \quad \|w\|_{l^{2}(X)} \equiv \left\{ \Delta t \sum_{n=1}^{N_{T}} \|w^{n}\|_{X}^{2} \right\}^{1/2},
\]

\[
\|w\|_{l^{0}(X)} \equiv \left\{ \Delta t \sum_{n=1}^{N_{T}} \|w^{n}\|_{X}^{2} \right\}^{1/2}.
\]
\[ ||w||_{^2_l(X)} \equiv \left\{ \Delta t \sum_{m=1}^{N_0} ||w^{m\alpha}||_{X}^2 + \sum_{n=2}^{N_T} (\Delta t_0 ||w^{n-\alpha}||_{X}^2 + \Delta t_1 ||w^n||_{X}^2) \right\}^{1/2}. \]

**Hypothesis 1.** There exists constants \( M_1, M_2, c_1 \) and \( c_2 \) independent of \( \Delta t, \alpha \) and \( h \) such that

\[ \begin{array}{l}
(1) \quad ||u_{h}||_{_\infty(W^{1,\infty})} \leq M_1, \\
(2) \quad X_1(u_{h}^{(m-1)\alpha}, \Delta t_1)(\Omega) \subset \Omega \quad (m = 1, \cdots , N_0), \quad X_1(u_{h}^{n-\alpha}, \Delta t_0)(\Omega) \subset \Omega \quad (n = 2, \cdots , N_T), \\
(3) \quad \forall n \quad (n = 2, \cdots , N_T), \quad \nu ||D(u_{h}^n)||^2 \leq \nu(1 + c_1 \Delta t_0) ||D(u_{h}^{n-\alpha})||^2 + c_2 ||f_{h}||^2, \\
(4) \quad ||\nabla p_{h}||_{L^2} \leq M_2.
\end{array} \]

**Proposition 1.** Let \((u_{h}, p_{h})\) be the solution of (2) with \( g = 0 \). Suppose that Hypothesis 1 holds. Then there exists a positive constant \( C \) independent of \( \Delta t, \alpha \) and \( h \) such that

\[ ||u_{h}||_{_{\infty(L^2)^d}} + \sqrt{\nu \Delta t_0} ||D(u_{h})||_{_{\infty(L^2)^d}} \leq C \left\{ ||u_{h}^0|| + \sqrt{ \nu \Delta t} ||D(u_{h}^0)|| + ||\nabla p_{h}||_{L^((L^2)^d)} + ||f_{h}||_{^2_l(X)} \right\}. \]

## 4 Numerical results

In this section we show numerical results in \( d = 2 \) with \( P2/P1 \) element. In [4] it is remarked that much attention should be paid to numerical integration of composite functions. We used a numerical integration formula of degree five on each triangle [3].

For a number \( N \in \mathbb{N} \) we set \( \Delta t \equiv 1/N \) and \( N_0 \equiv N + 1 \), i.e.,

\[ \Delta t = \frac{1}{N}, \quad \Delta t_0 = \frac{1}{N + 1}, \quad \Delta t_1 = \frac{1}{N(N + 1)}. \]

Since it holds that

\[ \Delta t_0 = O(\Delta t), \quad \Delta t_1 = O(\Delta t^2) \quad \text{as} \quad N \to +\infty, \]

the scheme (2) is of second order in \( \Delta t \).

To check the assumptions of Proposition 1, we solve the following example.

**Example 1.** We take \( \Omega = (-0.5, 0.5)^2 \), \( T = 1 \) and five values of \( \nu \),

\[ \nu = 1, \ 10^{-1}, \ 10^{-2}, \ 10^{-3}, \ 10^{-4}. \]

The functions \( f \), \( u^0 \) and \( g \) are given so that the exact solution is

\[ \begin{array}{l}
u = 1, \ 10^{-1}, \ 10^{-2}, \ 10^{-3}, \ 10^{-4}. \end{array} \]

\[ \begin{align*}
u_1(x_1, x_2, t) &= -4 \sin^2(2\pi t) \cos^4(\pi x_1) \cos^3(\pi x_2) \sin(\pi x_2), \\
u_2(x_1, x_2, t) &= 4 \sin^2(2\pi t) \cos^4(\pi x_1) \cos^4(\pi x_2) \sin(\pi x_1), \\
\nu p(x_1, x_2, t) &= \sin(2\pi(t + x_1 + x_2)).
\end{align*} \]

Let \( N_\Omega \) be the division number of each side of \( \Omega \), and we set \( N = N_\Omega \) in (3). We used almost uniform meshes with \( N_\Omega = 32, 40, 48, 56 \) by FreeFEM [5] (see Figure 2). When \( \nu = 10^{-4} \), \( M_1 \) decreased as \( N_\Omega \) increased from \( M_1 \approx 40 \) to 14. For the other
values of $\nu$, $M_1$ remained almost constant, $M_1 \approx 13$. We set $c_* \equiv \max\{c_1, c_2\}$. For each $\nu = 1, 10^{-1}, 10^{-2}, 10^{-3}$ and $10^{-4}$, $c_*$ was almost constant,

$$c_* \approx 2 \times 10^{-4}, \ 3 \times 10^{-4}, \ 3 \times 10^{-5}, \ 3 \times 10^{-6}, \ 3 \times 10^{-7},$$

respectively. $M_2$ remained almost constants,

$$M_2 \approx 6.3,$$

for every $\nu$.

Example 2 (a regularized cavity-flow). We take $\Omega = (0,1)^2, T = 500, f = 0, u^0 = 0$,

$$g_1(x_1, x_2, t) = \begin{cases} 16x_1^2(1-x_1)^2 \ (x_2 = 1) \\ 0 \ (x_2 \neq 1) \end{cases},$$

$g_2 = 0$ and three values of $\nu$,

$$\nu = 10^{-2}, 10^{-3}, 2 \times 10^{-4}.$$  

Reynolds number $Re (\equiv 1/\nu)$ equals to 100, 1,000 and 5,000, respectively. Considering the boundary layers, we used nonuniform meshes refined near the boundary. Figure 3 shows the meshes ($N_\Omega = 50$ for $Re = 100, 1,000, N_\Omega = 100$ for $Re = 5,000$).

We set $N = 10$ ($Re = 100, 1,000$), 20 ($Re = 5,000$) in (3), and total step numbers are 5,000 and 10,000, respectively. We computed (minimum) values, which satisfied (i)-(iv) of Hypothesis 1. For $Re = 100$, they were

$$M_1 \approx 92, \ c_* \approx 0.17, \ M_2 \approx 5.7.$$
For $Re = 1000$, they were

$$M_1 \approx 173, \quad c_* \approx 0.22, \quad M_2 \approx 4.1.$$ 

For $Re = 5000$, they were

$$M_1 \approx 398, \quad c_* \approx 0.24, \quad M_2 \approx 3.6.$$ 

At $t = 500$ every solution was almost stationary. Figure 4 exhibits the streamlines, which show the flow patterns well of this problem.

Figure 4: The streamlines of $Re = 100$ (left), $Re = 1,000$ (center) and $Re = 5,000$ (right)

5 Conclusions

We have presented a sufficient condition for the scheme (2) to be stable. In a numerical example we have seen the condition is reasonable. In another numerical example we have solved successfully a cavity flow problem with Reynolds numbers up to 5,000.
