Abstract

N-homoclinic bifurcations (N>2) are found and studied in a piecewise-linear vector field on $\mathbb{R}^3$.

1. Introduction

Consider a two parameter family of vector fields on $\mathbb{R}^n$:

$\dot{x} = F(x; \mu)$

Assume:

(i) $F(0, \mu) = 0, \mu \in \mathbb{R}^2, \mu = (\mu_1, \mu_2) \in \mathbb{R}^2$

(ii) $DF(x, \mu)$ has real eigenvalues $\lambda_1, \lambda_2, \lambda_3$ satisfying

$\text{Re}(\lambda_i) < \lambda_2 < \lambda_1 < 0 < \lambda_3 < \text{Re}(\lambda_j)$

where $\text{Re}(\lambda_i)$ indicates the real part of other eigenvalues.

(iii) The dynamics has a homoclinic orbit through the origin $x = 0$ at some $\mu$

Homoclinic doubling bifurcation is the phenomenon schematically drawn in Fig1. Namely, a homoclinic orbit of the simplest type (1-homoclinic) orbit bifurcates into a "double-loop" (2-homoclinic orbit) orbit.

![Fig1-1 Simplest homoclinic orbit](image1.png)  ![Fig1-2 Double-loop homoclinic orbit](image2.png)

Fig1 Schematic picture of homoclinic doubling bifurcation.

This phenomenon was first found and analyzed by Yanagida [1] during
Fig 2  Critically twisted homoclinic orbit

Fig 3  Non-principal homoclinic orbit
the course of his studies on generalized nerve axon equation. Analyzing with the original partial differential equation, Yanagida derived an ordinary differential equation and proved the existence of a double-pulse traveling wave solution, which corresponds to the homoclinic doubling bifurcation. Yanagida observed that there are three cases in which homoclinic doubling bifurcation can occur:

The original 1-homoclinic orbit is
(1) a homoclinic orbit with resonant eigenvalues, or
(2) a critically twisted homoclinic orbit, or
(3) a non-principal homoclinic orbit.

Case(1) refers to \( \lambda_1 + \lambda_3 = 0 \) while cases (2) and (3) are schematically shown in Fig2 and Fig3, respectively. M. Kisaka [3] proved that an \( N(>2) \)-homoclinic orbit does not bifurcate from a 1-homoclinic orbit in case (1) and (2). Nothing is known about \( N(>2) \)-homoclinic orbits for case (3), however. Details are found in [1],[2],[3],[4]. The purpose of this paper is to give an example which suggests that \( N(>2) \)-homoclinic orbit bifurcate from 1-homoclinic orbit for case(3).

2. Normal Forms of 2-Region Continuous Piecewise-Linear Vector Field.

Consider the 2-region continuous piecewise-linear vector field in \( \mathbb{R}^3 \):

\[
\dot{x}' = f(x') = \begin{cases} A'x' & (<\alpha', x'> - 1 \leq 0) \\ B'x' - p' & (<\alpha', x'> - 1 \geq 0) \end{cases}
\]

(2.1)

where \( A' \) and \( B' \) are 3\times3 matrices and \( p' \in \mathbb{R}^3 \). The plane \(<\alpha', x'>=1\) is the boundary of the vector field. Assume that \( A' \) has 3 real eigenvalues \( \lambda_1, \lambda_2, \lambda_3 \) (\( \lambda_3 > 0 > \lambda_1 > \lambda_2 \)) and \( B' \) has a pair of complex conjugate eigenvalues \( \sigma_1 + i\omega_1 \) and a real eigenvalue \( \gamma_1 \). (\( \sigma_1 < 0, \omega_1 > 0, \gamma_1 > 0 \)). According to the normal form theorem [5],[6], \( f \) is uniquely determined up to linearly conjugacy as follows (provided that \( f \) has no eigenspace parallel to the boundary):

\[
\dot{x}'' = S_A x'' + \frac{1}{2} p'' [ |<x'', x''| - 1 | + (<x'', x''| - 1) ]
\]

\[
= \begin{cases} S_A x'' & (x'' \in \mathbb{R}_-) \\ S_B (x'' - p'') & (x'' \in \mathbb{R}_+) \end{cases}
\]

(2.2)
where
\[ R_{\pm} = \{ x'' \in \mathbb{R}^3 : \pm(<\alpha'', x'' > -1) > 0 \} \]  
\[ \alpha'' = ^{T}(1, 0, 0) \]
\[ p'' = ^{T}(c_{1}, c_{2}, c_{3}) \]
\[ p'' = ^{T}(1 - \frac{a_{3}}{b_{3}}, \frac{c_{1}a_{3}}{b_{3}}, \frac{c_{2}a_{3}}{b_{3}}) \]

\[ S_{A} = \begin{bmatrix} 0 & 1 & 0 \\ a_{3} & a_{2} & a_{1} \end{bmatrix} \]
\[ S_{B} = \begin{bmatrix} c_{1} & 1 & 0 \\ c_{2} & 0 & 1 \\ c_{3} + a_{3} & a_{2} & a_{1} \end{bmatrix} = S_{A} + p''^{T}\alpha'' \]

\[ a_{1} = \lambda_{1} + \lambda_{2} + \lambda_{3}, a_{2} = -(\lambda_{1}\lambda_{2} + \lambda_{2}\lambda_{3} + \lambda_{3}\lambda_{1}), a_{3} = \lambda_{1}\lambda_{2}\lambda_{3} \]
\[ b_{1} = 2\sigma_{1} + \gamma_{1}, b_{2} = -(\sigma_{1}^{2} + \omega_{1}^{2} + 2\gamma_{1}\sigma_{1}), b_{3} = (\sigma_{1}^{2} + \omega_{1}^{2})\gamma_{1} \]
\[ c_{1} = b_{1} - a_{1}, c_{2} = b_{2} - a_{2} + c_{1}a_{1}, c_{3} = b_{3} - a_{3} + c_{1}a_{2} + c_{2}a_{1} \]

Fig. 4 shows the geometric structure of (2.2). The vector field defined by (2.2) is transformed via
\[ x'' = H_{A}x \]  
(2.3)
where
\[ H_{A} = \begin{bmatrix} 1 & 1 & 1 \\ \lambda_{1} & \lambda_{2} & \lambda_{3} \\ \lambda_{1}^{2} & \lambda_{2}^{2} & \lambda_{3}^{2} \end{bmatrix} \]
to the vector field

\[ \dot{x} = Ax + \frac{1}{2}p[|<\alpha, x > -1| + (<\alpha, x > -1)] \]

\[ = \begin{cases} Ax & (x \in \mathbb{R}_{-}) \\ B(x - p) & (x \in \mathbb{R}_{+}) \end{cases} \]  
(2.4)

where
\[ A = \begin{bmatrix} \lambda_{1} & 0 & 0 \\ 0 & \lambda_{2} & 0 \\ 0 & 0 & \lambda_{3} \end{bmatrix} \]
\[ \alpha = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, \quad p = H^{-1}_A p'' \quad P = B^{-1}p \]

\[ B = A + p^T \alpha \]

\[ R_\pm = \{ x \in \mathbb{R}^3 : \pm (\langle \alpha, x \rangle - 1) > 0 \} \]

\[ V = \{ x \in \mathbb{R}^3 : \langle \alpha, x \rangle = 1 \} \]

\[ V_- = \{ x \in V : \alpha^T \alpha x < 0 \} \]

\[ V_+ = \{ x \in V : \alpha^T \alpha x > 0 \} \]

This is called the normal form of 2-region continuous piecewise-linear vector field.

Fig5. shows the geometric structure of (2.4).

3.1 Return time coordinate.

Consider a point \( \tilde{X} \) lying on the boundary \( V \). Let \( \tilde{Y} \) and \( \tilde{Z} \) be the points at which the trajectory starting from \( \tilde{X} \) hits \( V \) again at positive time \( s \) and negative time \( -\tau \), respectively. Since the system is linear in each region, one has

\[ \tilde{y} = e^{Bs}(\tilde{x} - P) + P \quad (3.1.1) \]

\[ \tilde{z} = e^{-At}\tilde{x} \quad (3.1.2) \]

Since the vector field is continuous,

\[ A\tilde{x} = B(\tilde{x} - P) \quad \tilde{x} \in V \quad (3.1.3) \]

\[ A\tilde{y} = B(\tilde{y} - P) \quad \tilde{y} \in V \quad (3.1.4) \]

Using (3.1.4) and (3.1.1), one has

\[ A\tilde{y} = Be^{Bs}(\tilde{x} - P) \]

Since \( A \) is non-singular,

\[ \tilde{y} = A^{-1}e^{Bs}(\tilde{x} - P) \quad (3.1.5) \]

Moreover, by (3.1.3), one has

\[ \tilde{y} = A^{-1}e^{Bs}A\tilde{x} = e^{Cs}\tilde{x} \]

where

\[ C = A^{-1}BA \]

Since \( \tilde{X}, \tilde{Y} \) and \( \tilde{Z} \) are on the boundary \( V \)

\[ \alpha^T e^{-At}\tilde{x} = 1 \quad \alpha^T \tilde{x} = 1 \quad \alpha^T e^{Cs}\tilde{x} = 1 \]

so that

\[ \begin{pmatrix} e_1^T \alpha e^{-At} + e_2^T \alpha + e_3^T \alpha e^{Cs} \end{pmatrix} \tilde{x} = h \quad (3.1.6) \]

where

\[ e_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad e_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad e_3 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad h = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \]

If

\[ K(s, t) = \begin{pmatrix} e_1^T \alpha e^{-At} + e_2^T \alpha + e_3^T \alpha e^{Cs} \end{pmatrix}^{-1} \quad (3.1.7) \]
is non singular, then
\[ \tilde{x} = K(s, t)h \]  
(3.1.8)

The pair \((s, t)\) is called the return time coordinate of \(\tilde{x}\) on \(V\).
(See Fig. 6. and Fig. 7).

3.2 Homoclinic bifurcation equations.

If a trajectory starting from \((0, 1, 1)\) hits \(E^c(0)\) on the boundary \(V\), then it is a 1-homoclinic orbit through the origin (Fig. 4.) which is characterized by

\[
\begin{align*}
T\alpha e^{Cs}e_3 - 1 &= 0 \\
T_e e^{Cs}e_3 &= 0
\end{align*}
\]

(3.2.1)

Fig. 8. shows a 1-homoclinic orbit. Similarly, an \(N\)-homoclinic orbit through the origin is characterized by

\[
\begin{align*}
T\alpha e^{Cs}e_3 - 1 &= 0 \\
N(e^{Cs}e_3 - e^{-At}K(s_2, t_2)h) &= 0 \\
N(e^{Cs}K(s_i, t_i)h - e^{-At_i}K(s_{i+1}, t_{i+1})h) &= 0 \\
(2 \leq i \leq m - 1) \\
T_e e^{Cs}K(s_m, t_m)h &= 0
\end{align*}
\]

(3.2.2)

where

\[
N = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0
\end{bmatrix}
\]

Fig. 9 shows a typical 3-homoclinic orbit.

3.3 Tangent map

Assume that there exists an \(s_0\) such that
\[
\begin{align*}
z_0 &= e^{Bs}(y_0 - P) + P \quad (y_0 \in V_+, z_0 \in V_-), \\
T\alpha(e^{Bs}(y_0 - P) + P) - 1 &\neq 0 \quad \forall s \in (0, s_0)
\end{align*}
\]

Let
\[
H(y, s) = T\alpha((e^{Bs}(y - P)) + P) - 1
\]

Since
\[
H(y_0, s_0) = T\alpha z_0 - 1 = 0,
\]

and since
\[
\frac{\partial H}{\partial t}(y_0, s_0) = T\alpha Be^{Bs}(y_0 - P) = T\alpha B(z_0 - P) = T\alpha Az_0 \neq 0
\]

there exist a neighborhood \(V_+(y_0)\) of \(y_0\) on \(V_+\) and function (called a return time function)
\[
s: V_+(y_0) \rightarrow \mathbb{R}
\]
such that
\[ H(y,s(y)) = 0, s(y_0) = s_0. \]

Then,
\[ Ds(y_0) = -\left[ \frac{\partial H}{\partial t} (y_0, s_0) \right]^{-1} \frac{\partial H}{\partial y} (y_0, s_0) \]
\[ = -\left[ \alpha Az_0 \right]^{-1} T \alpha \epsilon^{B_0}. \]

Let
\[ g(y) = e^{B_0(y)} (y - p) + p. \]

Then one can show that the tangent map is given by,
\[ Dg(y_0) = Be^{B_0} (y_0 - p) Ds(y_0) + e^{B_0} \]
\[ = B (z_0 - p) Ds(y_0) + e^{B_0} \]
\[ = \left\{ I - \frac{Az_0}{\alpha} \right\} e^{B_0} \]
\[ = \left\{ I - \frac{Az_0}{\alpha} \right\} e^{B_0} \quad (3.3.1) \]

### 3.4 Conditions for homoclinic doubling bifurcation.

Define (See Fig10)
\[ h_1 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) = e_3 e^{B_0} e_3 \]
\[ h_2 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) = e_3 \left\{ I - \frac{Az_0}{\alpha} \right\} e^{B_0} (e_1 - e_3) \]
\[ \quad (3.4.1) \]

Then, a homoclinic doubling bifurcation is characterized by

1. Homoclinic orbit with resonant eigenvalues;
\[ h_1 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) \times h_2 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) < 0 \]
and
\[ |\lambda_1| = |\lambda_3| \]
\[ (3.4.2) \]

2. Critically twisted homoclinic orbit;
\[ h_2 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) = 0 \]
and
\[ |\lambda_1| < |\lambda_3| \]
\[ (3.4.3) \]

3. Non-principal homoclinic orbit;
\[ h_1 (\lambda_1, \lambda_2, \lambda_3, \sigma_1, \omega_1, \gamma_1) = 0 \]
and
\[ |\lambda_1| < |\lambda_3| \]
\[ (3.4.4) \]

### 4. Bifurcation sets of N-homoclinic orbits.

#### 4.1 Two parameter diagram.
Fig11 shows N-homoclinic bifurcation sets, for N=1~7, in the (λ₁, σ₁)-space obtained by solving (3.2.1) and (3.2.2). The vertical axis is σ₁ while the horizontal axis is λ₁. The other eigenvalues are fixed as
\[ \omega_1 = 1.0, \gamma_1 = -0.01, \lambda_2 = -0.32, \lambda_3 = 0.3 \quad (4.1.1) \]

Fig12 shows details of Fig11 where bifurcation sets for N=8 and 9 are discernible. Fig13 shows the same bifurcation sets in the range -0.8<λ₁<-0.4, whereas Fig14 shows details of Fig13. NH in these figures indicates N-homoclinic bifurcation sets. For N=3 and 5~9, homoclinic bifurcation sets form a loop while 4-homoclinic bifurcation sets consist of two loops. Moreover, it appears that all the N(3~9)-homoclinic bifurcation sets bifurcate from a point on the 1-homoclinic bifurcation set. Fig15 shows the orbits corresponding to the bifurcation sets. For 1H in Fig15, the numbers 1, 2 and 3 correspond to those in Fig3.

4.2 Non-principal homoclinic orbit.

Solving the set of Eqs.(3.2.1) and (3.4.4) by Newton method, we obtained the following set of values:
\[ \sigma_1 = 0.0137, \lambda_1 = -0.01 \]

These are the values on which non-principal homoclinic orbit exists. Now let us look at this point in Fig12. It appears that all the N(>2)-homoclinic bifurcation sets accumulate towards this point. This phenomenon suggests that there is a close relationship between N(>2)-homoclinic orbits and non-principal homoclinic orbit.

4.3 Three dimensional bifurcation diagram.

Fig16 shows a three dimensional bifurcation diagram of 3-homoclinic bifurcation set. Here γ₁ is fixed as γ₁=-0.04 while others are the same as in (4.1.1). This figure shows that 3-homoclinic bifurcation sets vanish if λ₂ is sufficiently larger than -0.3. Kisaka [3] proved under several conditions of eigenvalues including the case |λ₂| > |λ₃| that N(>2)-homoclinic orbit dose not bifurcate from 1-homoclinic orbit for the critically twisted case. This, however, dose not contradict our numerical results because for the latter, Kisaka's conditions are not satisfied.
