Abstract: The organocatalyzed asymmetric cyclopropanation of bromonitromethane with $\alpha$-cyano-$\alpha,\beta$-unsaturated imides is described. In addition, the same bifunctional thiourea was revealed to be a powerful catalyst for preparing these $\alpha$-cyanoimides by Knoevenagel condensation.

Key words: asymmetric organocatalysis, cyclopropanation, Michael addition, $\alpha,\beta$-unsaturated imides

2-Nitrocyclopropanecarboxylic acid derivatives are now recognized as versatile precursors for biologically active compounds. Furthermore, they are quite useful building blocks for the synthesis of highly functionalized molecular targets. Therefore, the catalytic and enantioselective construction of these motifs is a valuable challenge for synthetic chemists. Asymmetric Michael addition followed by intramolecular nucleophilic substitution is a representative process for this purpose. There have been several reports on the metal-free, organocatalyzed asymmetric synthesis of 2-nitrocyclopropane derivatives. Connon et al. reported the asymmetric cyclopropanation of nitroolefins with 2-iodomalonate via a chiral thiourea-catalyzed Michael addition followed by DBU-mediated intramolecular nucleophilic substitution. However, the enantioselectivity in these reactions was moderate and environmentally hazardous hexamethylphosphoramide (HMPA) was used in the second step. Recently, Fan et al. successfully applied the combined use of an aminothiourea catalyst and hypervalent iodine such as PhI(OAc)$_2$ to cyclopropanation, although this method was limited to the synthesis of malonate-derived cyclopropanes. Ley and Cordova independently developed a proline-mediated cyclopropanation of bromonitromethane to $\alpha,\beta$-unsaturated ketones or aldehydes. Although these reactions could be used for the efficient synthesis of the desired nitrocyclopropanes, these methods require an additional step for oxidation of the ketone or aldehyde into the corresponding carboxylic acids. Therefore, the development of a more direct and convenient protocol for preparing 2-nitrocyclopropanecarboxylic acids would be a considerable challenge.

We previously reported the enantioselective Michael addition of nitromethane to $\alpha,\beta$-unsaturated imides with bifunctional thiourea 1. We envisioned that if the same reaction with bromonitromethane proceeds efficiently, there is a chance that the Michael adduct obtained A would cyclize concurrently via the organocatalyzed intramolecular SN2 reaction, to give the desired 2-nitrocyclopropanecarboxylic acids stereoselectively. However, simple $\alpha,\beta$-unsaturated imides are not sufficiently electrophilic to react with the nucleophile. Therefore, we planned to introduce an additional small electron-withdrawing group such as CN at the $\alpha$-position of the substrates to possibly activate the Michael acceptor (Figure 1). In this report, we describe highly enantioselective organocatalyzed cyclopropanation with the use of novel Michael acceptors 4.

![Figure 1](https://repository.kulib.kyoto-u.ac.jp)
With the desired α,β-unsaturated nitriles 4a-e in hand, we next studied the nitrocyclopropanation of 4a-e with bromonitromethane in the presence of a stoichiometric amount of thiourea 1 (Table 2). The reaction of both methyl ester 4a and phenyl ketone took place smoothly at room temperature to give the corresponding nitrocyclopropanes 5a and 5b in moderate yields as a single product, respectively, but the enantioselectivities were low to moderate (entries 1 and 2). When α,β-unsaturated sulfone 4c was used as a substrate, the desired product 5c was not obtained at all (entry 3). In contrast to these results, the enantioselectivity was considerably improved with α,β-unsaturated oxazolidinone and imide 4d and 4e (entries 4 and 5). In the case of 4e, the major product 5e was obtained with 97% ee. Although inseparable epimer 6e was obtained as a minor product, 6e could be converted into 5e under basic conditions. The relative configuration of 5d was determined by X-ray crystallographic analysis, and the absolute configuration at C3 of 5a-e was assigned to be (R) according to our previous report. 

Based on the ee obtained, we selected 4e as the optimal Michael acceptor. To reduce the catalytic amount of 1, we next examined the catalytic asymmetric cyclopropanation of 4e in the presence of 10 mol% of 1 with several bases (Table 3). As expected, the catalytic reaction with no additional base resulted in the recovery of most of the starting material and gave the cycloadduct 5e in 11% yield with small amounts of Michael adduct (4%) (entry 1). Although the addition of 1.5 equiv of inorganic bases such as NaHCO₃ and K₂CO₃ improved the yield of 5e to 37 and 27% without producing 6e, the reaction did not proceed effectively due to the low solubility of the bases in toluene (entries 2 and 3). Furthermore, pyridine was too weak as a base for the reaction (entry 4). After several investigations of bases, Et₃N was found to be the best additive, and gave 5e in 55% yield as a single product (entry 5). The excellent enantioselectivity of the product was still maintained in the catalytic reaction even with an excess amount of an achiral base such as Et₃N. On the other hand, when the same reaction was performed at lower temperature, the chemical yield was enhanced to 84% and we obtained a mixture of 5e and diastereoisomer 7e, which was an C3 epimer of 5e, in a ratio of 63:37 (entry 6). The relative configuration of 7e was deduced from the ¹H NMR spectrum. The mechanism of the generation of 7e with a decrease in the reaction temperature is unclear at this stage, but might be attributed to deceleration of the cyclization of the Michael adduct at low temperature.
We finally investigated the scope of this catalytic reaction with several α,β-unsaturated α-cyanoimides 4f-4k bearing different aryl groups as the β-substituent under the optimized conditions (Table 4).15 Regardless of the electron-withdrawing or electron-donating groups of the aryl group, the catalytic reaction of 4f-g and 4j proceeded in good yield without affecting the stereoselectivity (entries 1, 2 and 5). The substituted position (α-, m-, p-) of the chloride group did not significantly affect either the chemical yield or the ee (entries 2-4). Furthermore, imide 4k bearing a naphthyl group could be converted to the corresponding cyclopropane 5k in excellent ee. Although the diastereoselectivity should be improved, we have developed the thiourea-catalyzed enantiosselective cyclopropanation of bromonitromethane and α,β-unsaturated imides 4 in the presence of Et3N.

In conclusion, we have developed highly reactive and stereoselective Michael acceptors such as 4e-g. These substrates could be easily prepared by Knoevenagel condensation with bifunctional thiourea. Optically active 2-nitrocyclopropanecarboxylic acids were also synthesized with the same thiourea in excellent enantioselectivities.

Knoevenagel reaction catalyzed by thiourea 1
A mixture of 3e (40.2 mg, 0.195 mmol), benzaldehyde 2a (22 μL, 0.215 mmol), and (rac)-thiourea 1 (8.1 mg, 0.0195 mmol) in toluene (2.0 mL) was stirred at 80 °C for 25 h. After the reaction mixture was concentrated in vacuo, the residue was purified by silica gel column chromatography with Hexane/EtOAc (3/1) to afford 4e (41.5 mg, 72%) as white needles.

(E)-N-[2-Cyano-3-phenylacyrloyl]-2-fluorobenzamide (4e)
White needles; Rf = 0.54 (Hexane:EtOAc, 1:1); m.p 186-188°C; 1H NMR (500 Mz, CDCl3): δ = 9.94 (d, J = 16.3 Hz, 1H), 8.47 (s, 1H), 8.16 (td, J = 6.3, 1.7 Hz, 1H), 8.02 (d, J = 8.0 Hz, 2H), 7.65-7.60 (m, 2H), 7.55 (dd, J = 8.0, 7.2 Hz, 2H), 7.36 (dd, J = 7.7, 7.2 Hz, 1H), 7.25 (dd, J = 12.0, 8.0 Hz, 2H). 13C NMR (126 Mz, CDCl3): δ = 161.5, 161.0 (2C), 160.6 (d, J = 249 Hz), 158.3, 156.4, 153.6 (d, J = 9.9 Hz), 133.9, 132.7, 131.3, 129.2, 125.6 (d, J = 3.0 Hz), 116.0 (d, J = 10.2 Hz), 116.5 (d, J = 24.6 Hz), 114.0, 103.4.
