it is worthy to know many different proofs of the two variables case. Because of this reason, I am giving here my proof of the two variables case and also some comments on the general case.

Thanks are due to Professor Abhyankar, Professor Zariski for their valuable informations on the problem; to my friends at Purdue University for their discussion on the problem; to Mrs. Hayashi for type-writing the manuscript.

## Part 0 Introduction and preliminaries.

Introduction.

By a ring, we sha11 mean a comutative ring with identity throughout this article.

Let $k$ be a ring and let $k[x]=k\left[x_{1}, \ldots, x_{n}\right]$ be the polynomial ring in $n$ variables $x_{1}, \ldots, x_{n}$ over $k$. Then the question which we shall deal with is on the structure of the group of automorphisms Aut $k[x]$ over $k, k$ and $k[x]$ will maintain these meanings throughout this article.

We shall begin with looking at some special subgroups of Aut $k[x]$.
Linear subgroups. Let us consider the general linear group GL( $n, k$ ) over $k$. An arbitrary element $\sigma \varepsilon G L(n, k)$ defines a k-automorphism of $k[x]$ so that

$$
\left(\sigma x_{1}, \ldots, \sigma x_{n}\right)=\left(x_{1}, \ldots, x_{n}\right) \sigma
$$

where the right hand side is understood by matric multiplication. Note that if $\sigma, \tau \varepsilon G L(n, k)$, then $\left(\sigma\left(\tau x_{1}\right), \ldots, \sigma\left(\tau x_{n}\right)\right)=\sigma\left[\left(x_{1}, \ldots, x_{n}\right) \tau\right]$ $=\left(\sigma x_{1}, \ldots, \sigma x_{n}\right) \tau=\left(x_{1}, \ldots, x_{n}\right) \sigma \tau$. Thus we may regard that the general linear group $G L(n, k)$ is a subgroup of $A u t_{k} k[x]$. Furthermore, we can observe affine transformations similarly. Namely, an affine transformation of the $n$-space is defined by a sequence of
an element, say $\sigma$, of $G L(n, k)$ and $n$ elements, say $c_{1}, \ldots, c_{n}$, of $k$. Such an affine transformation defines also a k-automorphism such that $x_{i}$ is sent to $\sigma x_{i}+c_{i}$. Thus the affine transformation group $A(n, k)$ can be regarded as a subgroup of $A u t{ }_{k} k[x]$.

Jonquières automorphisms. When $a_{1}, \ldots, a_{n}$ are units in $k$ and $f_{i} \varepsilon k\left[x_{i+1}, \ldots, x_{n}\right]$ for $i=1, \ldots, n \quad\left(f_{n} \varepsilon k\right)$, then there is an element $\tau$ of Aut $k[x]$ such that $\tau x_{i}=a_{i} x_{i}+f_{i}(i=1, \ldots, n)$.

This type of automorphism is called a Jonquieres automorphism of $k[x]$. The set $J(n, k)$ of all Jonquieres automorphisms of $k[x]$ is a subgroup of $\mathrm{Aut}_{k} \mathrm{k}[\mathrm{x}]$.

As we shall show later $(\S 0.2)$, it holds that :

Theorem 0.1. Let $g_{1}, \ldots, g_{n}$ be nilpotent elements of $k[x]$.
Then there is a $\sigma \in$ Aut $_{k} k[x]$ such that $\sigma x_{i}=x_{i}+g_{i}(i=1, \ldots, n)$.

The set of all automorphisms of this type forms a subgroup of

Aut ${ }_{k} k[x]$ and is called the subgroup of nilpotency of $A u t_{k} k[x]$. We shall denote it by $N(n, k)$. As for this subgroup, it holds that :

Proposition 0.2 . Let $\sqrt{0}$ be the nil-radical of $k$ and we consider the natural homomorphism $\psi:$ Aut $_{k} k[x] \longrightarrow$ Aut $_{k / \sqrt{0}}(k / \sqrt{0})[x]$. Then $\psi$ is a surjection and $N(n, k)$ is the kernel of $\psi$.

The proof will be given later in $\S 0.2$.

Now, one particular problem in our question is :

Qestion 0.3. Is $A u t_{k} k[x]$ generated by $G L(n, k), J(n, k)$ and $N(\mathrm{n}, \mathrm{k})$ ?

Unfortunately, the answer is negative in the general case as will be shown in Part 2. Part 1 of the article contains a proof of the following theorem, which should be called a theorem of Jung-van der Kulk (cf. § 0.1 ), and also a structure theorem of $A u t_{k} k[x]$ due to van der $K u l k$.

Theorem 0.4. The question 0.3 is affirmative if $k$ is a field and if $n=2$ 。

On the other hand, it is obvious that

Lemma 0.5. If $k$ is the direct sum of rings $k_{1}, \ldots, k_{s}$, then Aut $k[x]$ is the direct product of $A u t_{k_{i}} k_{i}[x] \quad(i=1, \ldots, s)$.

In view of Proposition 0.2 and Lemma 0.5 above, we have

Corollary 0.6. The question 0.3 is affirmative if $n=2$ and if $k$ is an Artin ring.

Part 2 contains some results related to the question in case either $n \neq 2$ or $k$ is not an Artin ring.
0.1 Historical remarks on the problem.

The case where $n=1$ and $k$ is a field is well known and easy ; even if $k$ is not a field, if $n=1$, then $A_{k} k[x]$ has fairly simple structure (cf. § 0.3).

In the past, mostly the case where $k$ is a field and $n=2$ has
been treated. In that case, an affirmative answer of the question 0.3 was claimed by Jung [4] in 1941, in the classical case. Some related questions in the classical case were treated also by some authors including Engel [2] and Gutwirth [3]. But I am afraid that their treatments are too difficult to follow. Meanwhile, van der Kulk [6] gave a much better treatment and proved our Question 0.3 for $n=2$ and $k$ an arbitrary field. Recently, Abhyankar-Moh [1] treated the question from another aspect. Namely, as one will see later in this article, the question has very close relationship with the following classical conjecture :

Conjecture 1.1. Let. C be an irreducible curve on an affine plane $S$ defined by $f(x, y) \varepsilon k[x, y]$. Assume that $C$ is biregular to an affine line, namely, $k[x, y] /(f) \cong k[t]$. Then there is a polynomial $g(x, y)$ such that $k[x, y]=k[f, g]$.

As was shown by the writer [8], this conjecture is not affirmative in the positive characteristic case, hence the conjecture was modified : Modified conjecture 1.2. Add one assumption that $\operatorname{deg} f$ is not divisible by the characteristic of the ground field $k$. Then the assertion in the conjecture holds good.

One of important results in [1] is an affirmative answer of this modified conjecture.

On the other hand, our treatment is very different from those given
by these authors : We are to make use of nice behaviour of birational correspondences of non-singular projective surfaces.
0.2 Some easy results related to the statements in Introduction. To begin with, we shall prove a well known lemma : Lemma 2.1. Let $M$ be a $k$-module and let $N$ be a submodule of $M$. If $I$ is a nilpotent ideal of $k$ and if $M=N+I M$, then $M=N$. Proof. $M=N+I M=N+I(N+I M)=N+I^{2} M$. Similarly, $M=N+I^{T} M$ for every natural number $r$. Because of the nilpotency of $I$, we have $M=N$. q.e.d.

| Proposition 2.2. Consider $n$ elements $\dot{y}_{1}, \ldots, y_{n}$ of the |
| :---: |
| polynomial ring $k[x]$. If $k[y]=k[x]$, then $k[y]$ is a polynomial ring, |
| i.e., $F(x) \in k[x], F(y)=0$ imply $F(x)=0$. Hence there is a |
| k.-automorphism $\sigma$ of $k[x]$ such that $\sigma x_{i}=y_{i}(i=1,2, \ldots, n)$. |
| Proof. Assuming the contrary, let $F(x)(\neq 0)$ be such that |
| $F(y)=0$, Since $k[y]=k[x]$, there are polynomials $f_{1}(x), \ldots, f_{n}(x)$ |
| such that $\mathrm{x}_{i}=\mathrm{f}_{i}(\mathrm{y})$. Let $\mathrm{k}^{\prime}$, be the subring of $k$ generated by the |
| coefficients of $1, F(x), y_{1}, \ldots, y_{n}, f_{1}(x), \ldots, f_{n}(x)$. Then $k^{\prime}$ |
| is noetherian, because $\mathrm{k}^{\prime}$ is finitely generated. Therefore, considering |
| $k^{\prime}$ instead of $k$, it suffices to prove the assertion under the additional |
| assumption that $k$ is noetherian. Let $\phi$ be the $k$-surjection given by |
| $\phi x_{i}=y_{i}(i=1, \ldots, n)$. Then powers $\phi^{r}$ are also $k$-homomorphisms. |

Let $I_{r}$ be the kernel of $\phi^{r}$. Since $k$ is noetherian, there is one $r$, say $s$, such that $I_{s}=I_{s+1}=\ldots$. Let $a$ be an arbitrary element of $I_{s}$. Since $\phi^{s}$ is a surjection, there is an element $b$ of $k[x]$ such that $a=\phi^{s}(b)$. Then we see that $0=\phi^{s}(a)=\phi^{2 s}(b)$. Hence $b \varepsilon I_{2 s}=I_{s}$. This implies that $a=\phi^{s}(b) \varepsilon \phi^{s}\left(I_{s}\right)=\{0\}$. Thus $I_{s}=\{0\}$ and we see that $\phi$ is an automorphism. q.e.d. As a corollary to these two results, we have :

Proposition 2.3. Let $y_{1}, \ldots, y_{n} \varepsilon k[x]$ be such that they generate $k[x]$ over $k$ modulo the nil-radical, i.e. ( $k[y]$ modulo the nilradical $)=(k[x]$ modulo the nil-radical), then $k[x]=k[y]$ and there is a k-automorphism $\sigma$ such that $\sigma \mathrm{x}_{\mathrm{i}}=\mathrm{y}_{\mathbf{i}} \quad(\mathbf{i}=1, \ldots, \mathrm{n})$. Proof. $\quad x_{i}=t_{i}+\sum_{j=1}^{s} c_{i j} z_{i j} \quad\left(t_{i} \varepsilon k[y], \quad c_{i j} \varepsilon\right.$ (the nilradical of $\left.k), z_{i j} \varepsilon k[x]\right)$. Let $N$ be the ideal generated by these $c_{i j}$ $\left(i=1, \ldots, n ; j=1, \ldots, s_{i}\right)$. Then $N$ is nilpotent and therefore $k[x]=k[y]$ by Lemma 2.1. Therefore we have the result by Proposition 2.2.
q.e.d.

Now, let us prove Theorem 0.1. Setting $y_{i}=x_{i}+g_{i}$, we see that Proposition 2.3.is applied immediately, and we have the theorem.

Next, let us prove Proposition 0.2. If $\tau \varepsilon \operatorname{Aut}_{k / \sqrt{0}}(k / \sqrt{0})[x]$, then let $y_{i}$ be an element of $k[x]$ such that $\left(y_{i}\right.$ modulo $\left.\sqrt{0}\right)=$ $\tau X_{i}$. Then Proposition 2.3 implies that there is $\sigma \varepsilon A u t_{k} k[x]$ such
that $\sigma \mathbf{x}_{\mathbf{i}}=\mathrm{y}_{\mathrm{i}}$. Thus $\phi$ is a surjection. It is obvious that $\mathrm{N}(\mathrm{n}, \mathrm{k})$ is the kernel of $\phi$. q.e.d.
0.3 The easy case, $n=1$.

Proposition 3.1. If $n=1$, then $A u t_{k} k[x]$ is generated by $A(1, k)$ and $N(1, k)$. More precisely, there is a one-one correspondence between $A u t_{k} k[x]$ and the set $M=\{(a, b, f) \mid a=a$ unit in $k, b \varepsilon k, f=a$ nilpotent element in $k[x]\}$ in such a way that $\sigma$ corresponds to ( $a, b, f$ ) if $\sigma x=a x+b+f$ 。

Proof. In view of Proposition 0.2 , we may assume that $\sqrt{0}=\{0\}$. It is obvious that for a given $(a, b, 0) \varepsilon M$, there is a $\sigma \varepsilon A u t_{k} k[x]$ such that $a x+b=\sigma x$. Let $\tau$ be an arbitrary element of Aut $k[x]$ and write $\tau x=c_{0}+c_{1} x+\ldots+c_{s} x^{s}\left(c_{i} \varepsilon k, c_{s} \neq 0\right)$. Since there is an $F(x) \quad k[x]$ such that $F(\tau x)=x$, we must have $s=1$ and deg $F(x)=1$ (by our assumption that $\sqrt{0}=\{0\}$ ). Therefore we see also that $c_{1}$ is a unit in $k$. q.e.d.
0.4 Prerequisites, notation and terminology.

Notation introduced in the introduction above is maintained. When we consider two irreducible algebraic surfaces $V, W$ having the same function field, we identify points $P(\varepsilon V)$ with $Q(\varepsilon W)$ if they correspond biregularly under the natural birational correspondence
(i.e., if their local rings over a field $K$ of definition over which they are rational coincides with each other). In this sense, the quadratic dilatation $d i l_{P} V$ of $V$ with center $P$ is well defined. When a successive quadratic dilatation with centers $\mathrm{P}_{1}, \ldots, \mathrm{P}_{\mathrm{n}}$ is defined on $V$, then the transformation is denoted by $\mathrm{dil}_{\mathrm{P}_{1}} \ldots \mathrm{P}_{\mathrm{n}}$. Hence $\operatorname{dil}_{P_{1}} \ldots P_{n}={ }^{d i I_{P}}{ }_{n} \cdot{ }^{d i I_{P_{1}}} \ldots P_{n-1}$

We are assumed to be familiar with basic facts on birational correspondences of non-singular projective surfaces.

A point of $V$ in the usual sense is called an ordinary point of $V$. By a point of $V$, we understand that it is either an ordinary point or an infinitely near point $V$ : as for the notion of an infinitely near point, we shall review it in $\S 0.5$.

Let $C$ be an irreducible curve on $V$. A point $P$ of $C$ ( being an ordinary point of $V$ ) is called a one-place point of $C$ if the derived normal ring of the local ring of $P$ on $C$ is local ; this means that if $W$ is a surface birationally dominating $V$ and if ordinary points $Q$, $Q^{\prime}$ of $W$, corresponding to $P$, lies on the proper transform of $C$, then $Q=Q^{\prime}$.
$\Omega$ denotes a universal domain which we shall fix, and $\Omega^{2}$ denotes the affine plane (over $\Omega$ ). $\mathbb{P}^{2}$ denotes a projective plane. Using coordinates system $(X, Y, Z)$ on $\mathbb{E}^{2}$, the line $Z=0$ is supposed to
be the line at infinity and is denoted by $\ell_{\infty}$. The complement of the line is identified with $\Omega^{2}$.

When $V$ is an irreducible algebraic variety defined over a field $K$, the function field of $V$ over $K$ is denoted by $K(V)$.

Let $V$ and $W$ are non-singular varieties such that $W$ dominates $V$. Let $T$ be the correspondence $V \longrightarrow W$. If $D$ is a divisor on $V$, then the total transform of $D$ is denoted by $T\{D\}$; the proper transform of $D$ is denoted by $T[D]$. Note that $T\{D\}$ is defined by local equations, namely, if $Q$ dominates $P$ under $T^{-1}$, then (the local equation of $T\{D\}$ at $Q$ ) $=$ (the local equation of $D$ at $P$ ). Therefore the total. transform $T\}$ preserves linear equivalence.

Linear equivalence of divisors is expressed by the symbol $\sim$.

### 0.5 Infinitely near points.

One remarkable fact on birational transformations of non-singular projective surfaces is as follows :

Theorem 5.1. Let $V$ and $W$ be non-singular projective surfaces having the same function field. If an ordinary point $P$ is dominated by an ordinary point $Q$ of $W$, then there is a sequence $P=P_{0}, \ldots, P_{n}$ such that (i) $Q=P_{n}$ and (ii) for each $i>0, d i 1_{P_{0}} \ldots P_{i-1}$ is well

dominates $\mathrm{P}_{\text {i-1 }}$.
In this case, $Q$ is called an infinitely near point to $P$ of order n.

Infinitely near points to $P$ of order one correspond to tangential directions around $P$. Namely, letting $t$ and $u$ be local coordinates at $P$, we consider the local equation of a curve $C$ at $P$ :
(5.2) $\quad \sum_{i+j=m} c_{i j} t^{i} u^{j}+$ (terms of higher orders)
with $c_{i j} \varepsilon k, m>0$. The term $h(t, u)=\Sigma c_{i j} t^{i} u^{j}$ gives (besides that $P$ is an $m$-ple point of $C$ ) tangential directions of branches of C at P ; C has a branch of tangential direction $\mathrm{t}=\alpha \mathrm{u}(\alpha \varepsilon \Omega)$ if and only if $t-\alpha u$ is a factor of $h(t, u)$. On $d i l_{p} V$, if $t / u=\alpha$ at a point $P^{\prime}$ of $\mathrm{dil}_{P} P$, then the local equation of the total transform $C^{*}$ of $C$ at $P^{\prime}$ is

$$
u^{m} h(t / u, 1)+u^{m+1} g(u, t / u)
$$

with some polynomial g. Therefore it is factored to $u^{m}$ and (5.3) $h(t / u, 1)+u g(u, t / u)$.

Since $u$ at $P^{\prime}$ gives $\mathrm{dil}_{P} P, C^{*}$ is of the form $m \cdot d i l_{P} P+C_{1}$ with a curve $C_{1}$ whose local equation at $P^{\prime}$ is (5.3). $C_{1}$ goes through $P^{\prime}$ obviously because $h(t, u)$ is a homogeneous form having $t-\alpha u$ as a factor. Furthermore, if $m$ is the exact multiplicity of $P$ on $C$,
then, the intersection multiplicity of $C_{1}$ with dil $_{P} P$, coincides with the multiplicity of the factor $t-\alpha u$ in $h(t, u)$, because, in view of the fact that $u$ defines $\operatorname{dil}_{p} P$, we see that the former coincides with the intersection multiplicity of the curve $h(t / u, 1)=0$ with $\operatorname{dil}_{P} P$ at $P^{\prime}$. Thus we obtained also the following :

Proposition 5.4. If a curve $C$ goes through an ordinary point $P$ of $V$ with multiplicity exactly $m$, then letting $C_{1}$ denote the proper transform of $C$ on $\operatorname{dil}_{P} V$, we see that
(1) The total transform $\mathrm{di} l_{\mathrm{P}} \mathrm{C}$ of C is equal to $\mathrm{C}_{1}+\mathrm{m} \cdot \mathrm{di} 1_{\mathrm{P}} \mathrm{P}$
(2) the intersection number $\left(C_{1}, d i l_{P} P\right)$ is equal to $m$.

We note here that the intersection number of two divisors $C^{\prime}, C^{\prime \prime}$ coincides with that of total transforms of $C^{\prime \prime}, C^{\prime \prime}$.

Proposition 5.5. With the same notation as above, we have
(1) $\quad\left(\mathrm{dil}_{\mathrm{P}} \mathrm{P}, \mathrm{diI}_{\mathrm{P}} \mathrm{P}\right)=-1$.
(2) $\quad\left(C_{1}, C_{1}\right)=(C, C)-m^{2}$

Proof. Since $C \sim C^{\prime}-C^{\prime \prime}\left(C^{\prime}, C^{\prime \prime}\right.$ are positive divisors) such
 $=0$. Hence $0=\left(C_{1}+m d i l_{P} P, d i I_{P} P\right)=m+m\left(d i l_{P} P, d i I_{P} P\right)$, and we have (1). ( $\mathrm{C}, \mathrm{C})=\left(\mathrm{C}_{1}+\mathrm{mdi} \mathrm{di}_{\mathrm{P}} \mathrm{P}, \mathrm{C}_{1}+\mathrm{mdil} \mathrm{di}_{\mathrm{P}} \mathrm{P}\right)=\left(\mathrm{C}_{1}, \mathrm{C}_{1}\right)+$ $2 m\left(C_{1}, d i I_{P} P\right)+m^{2}\left(d i 1_{P} P\right)=\left(C_{1}, C_{1}\right)+2 m^{2}-m^{2}=\left(C_{1}, C_{1}\right)+m^{2}$. q.e.d.

Remark 5.6. Proofs of these two propositions may be done as follows : Proposition 5.4, (1) is proved first. Then considering a special case where $m=1$, we obtain Proposition 5.5, (1). Then we have Proposition 5.4, (2) by :

$$
0=\left(C_{1}+m \operatorname{di1}_{P} P, \operatorname{di1} P_{P} P\right)=\left(C_{1}, \operatorname{di1}_{P} P\right)+m\left(d i 1_{P} P, d i 1_{P} P\right)
$$

Here we add a remark on the case where $m$ is not the exact multiplicity. We consider the condition on curves $C$ such that $C$ goes through $P$ as an $m$-ple point and furthermore $C$ goes through certain infinitely near points $O_{1}, \ldots, Q_{s}$ of order one to $P$, for instance. It is quite natural to understand this condition to be the condition on the local equation of $C$ at $P$ to be such that it is of the form (5.2) and the form $h(t, u)=\Sigma c_{i j} t^{i} u^{j}$ has factors corresponding to $Q_{1}, \ldots, Q_{s}$. Actually, if we look at a linear system of curves on V and consider those members of L satisfying the above condition, then the subset of such members is a well defined linear system under this understanding. If a $C$ goes through $P$ with multiplicity bigger than $m$, then $h(t, u)=0$ whence the condition is satisfied by this $C$. This means that if the multiplicity of $P$ is higher, then the condition stated above do not imply that the curve has branches corresponding to $Q_{1}$. One extreme case is the case where $s>m$. Since $h$ is of
degree $m$, it cannot have more than $m$ factors unless it is zero. Therefore, as the actual effect, the condition " to go through $P$ with multiplicity $m$ and furthermore goes through $m+1$ distinct infinitely near points of order one to $P$ " is equivalent to the condition " to go through $P$ with multiplicity $m+1$.

Therefore we must be careful of the term " to go through ", and therefore we shall define the term after some preliminaries.

First, we define divisorial cycles in very generalized way. Namely, let $D c_{0}(V)$ be the set of point of $V$ (including infinitely near points) and let $D c_{1}(V)$ be the set of irreducible curves on $V$. Let $D c(V)$ be the free module generated by $D c_{0}(V) V D c_{1}(V)$ over $\mathbb{Z}$. This module Dc(V) js called the divisorial cycle group of $V$ and each member of it is called a divisorial cycle on $V$.

When $P$ is an ordinary point of $V$, we define a group homomorphism $\mathrm{Dc}(\mathrm{V}) \longrightarrow \mathrm{Dc}\left(\mathrm{dil}_{\mathrm{P}} \mathrm{V}\right)$ by
(i) if $C \in D c_{1}(V)$, then $C$ is mapped to its total transform (in the usual sense),
(ii) $P$ is mapped to its total transform $\mathrm{dil}_{P} P$,
(iii) if $P \neq Q \in D c_{0}(V)$, then $Q$ is mapped $Q$ itself.

We shall denote this homomorphism by the same symbol $\mathrm{dil}_{\mathrm{P}}$ as the birational transformation. One sees quite easily that $\mathrm{dil}_{\mathrm{p}}$ gives an isomorphism.

If $W$ is a nonsingular projective surface having the same function field as $V$, birational transformation $\tau: V \longrightarrow W$ is factored to the form
with fundamental points $Q_{1}, \ldots, Q_{r}$ on $W$ with respect to $V$ and fundamental points $P_{1}, \ldots, P_{S}$ on $\nabla$ with respect to $W$. Therefore by composing isomorphisms ${ }^{d i l_{P_{i}}}$ and ${ }^{d i 1_{Q_{j}}}{ }^{-1}$, we obtain an isomorphism $D c(V) \longrightarrow D c(W)$, which we shall denote by $T$ again. Then, one sees easily that if the birational transformation $T$ is the composition of two birational transformations $\mathrm{T}_{1}, \mathrm{~T}_{2}$, then the corresponding isomorphism $T$ is also the composition of corresponding isomorphisms to $T_{1}, T_{2}$. For $c \varepsilon \operatorname{Dc}(\mathrm{~V}), \mathrm{Tc}$ is called the total transform of c on $W$. Secondly, we define positivity of divisorial cycles as follows : An element $c \varepsilon \operatorname{Dc}(V)$ is called virtually positive if all of the coefficients of $c$ are non-negative. (Note that element 0 is virtually positive under this definition.) An element $c \varepsilon \operatorname{Dc}(V)$ is called
 such that $\mathrm{T}_{\mathrm{c}}$ is virtually positive.

Now we define " to go through ". A curve $C$ on $V$ is said to go through $\sum_{i=1}^{s} m_{i} P_{i} \quad\left(m_{i} \varepsilon Z, P_{i}\right.$ points of V) if $C-\sum m_{i} P_{i}$ is effectively positive.

We add here another definition. A point $P$ of $V$ is said to lie on a curve $C$, if, letting $P_{0}, \ldots, P_{r}=P$ be the sequence of points of $V$ such that $P_{0}$ is an ordinary point and each $P_{i}$ ( $i>0$ ) is an infinitely near point of order one to $P_{i-1}, P$ lies on the proper transform $C *$ of $C$ on $\mathrm{dil}_{\mathrm{P}_{0} \ldots \mathrm{P}_{\mathrm{r}-1}} \mathrm{~V}$. The effective multiplicity of $P$ on $C$ in this case is defined by the multiplicity of $P$ on $C *$.

We now observe a linear system $L$ on $V . L$ is a set of positive divisors and is defined by a pair of a finite k-submodule of $k(V)$ and a divisor $D$ on $V$ so that $L=\{D+(f) \mid 0 \neq f \varepsilon M\}$. Consider the birational correspondence $T: V \longrightarrow W$. We define effective transform $T_{e f}^{L}$ of $L$ on $W$ to be the uniquely determined linear system by the properties that (i) it has no fixed component and (ii) the same module $M$ is associated to it. On the other hand, we define total transform of $L$. For the purpose, we generalize the notion of a linear system a little. Namely, we consider symbols of type $L-\sum m_{i} P_{i}$, where $L$ is a linear system, $m_{i} \varepsilon Z$ and $P_{i} \varepsilon D c_{0}(V)$. To this symbol, we associate $\left\{D-\Sigma m_{i} P_{i} \mid D \varepsilon L, D-\Sigma m_{i} P_{i}\right.$ effectively positive $\}$, which is a set of effectively positive divisorial cycles. The total transform of $L-\sum m_{i} P_{i}$ is defined to be the set of total transforms of these effectively positive divisorial cycles. Remarks to be given here are :

Remark 5.7. If $T$ is regular, then the total transform $T L$ of
$L$ is of the form $L^{*}-\sum m_{i} P_{i}^{\prime}$ ( $L^{*}$ a linear system ; $P_{i}^{\prime} \varepsilon D c_{0}(W)$ ). $\mathrm{m}_{\alpha}<0$ implies that the total transform of $\mathrm{P}_{i}^{\prime}$ is a fixed component of $L$.

Remark 5.8. In general, if $L$ has no fixed component, then

$$
T L=\left(T e^{L}+D\right)-\Sigma m_{i} P_{i}^{\prime}
$$

with a positive divisor $D, m_{i} \varepsilon \mathbb{Z}, P_{i}^{\prime} \varepsilon D c_{0}(W)$, and for every member of $T_{e f} L+D$, the multiplicity of $P_{i}^{\prime}$ on it is at least $m_{i}$.

Remark 5.9. As for $L-\Sigma m_{i} P_{i}$ above, if $\operatorname{dil}_{Q_{1}} \ldots Q_{r}$ is well defined on $V$ and if every $P_{i}$ is among these $Q_{j}$, then the total transform ${ }^{d i 1} Q_{1} \ldots Q_{r}\left(\mathrm{~L}-\Sigma \mathrm{m}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}}\right)$ is a linear system.

By virtue of Remark 5.8, we can see the following fact :
Remark 5.10. Let $L$ be a linear system on $V$. If $L$ has no fixed component and if $\mathrm{T}_{\mathrm{ef}} \mathrm{L}^{\mathrm{L}}$ has no fixed point, then

$$
T_{e f} L=T\left(L-\Sigma m_{i} P_{i}\right)
$$

where the $P_{i}$ are fixed points of $L_{\text {a }}$ and $m_{i}$ is the multiplicity of $P_{i}$ on a general member of $L$. Consequently, each $P_{i}$ is fundamental with respect to W .

As a corollary to this, we have the following remark, which we are going to use later :

Remark 5.11. Let $L$ be a 1inear system on V. Assume that $L$ has no fixed component. If $T_{e f} \mathrm{~L}$ consists only of non-singular curves and if $T_{e f} \mathrm{~L}$ has only one fixed point $Q$, then
(I) Singular points of a member of $L$ are fundamental with respect to $T$ and are fixed points of $L$.
(2) A fixed point of $L$ is either a fundamental point with respect to $T$ or $Q$ itself ; if $Q$ is fundamental with respect to $T^{-1}$, then every fixed point of $L$ is fundamental with respect to $T$.

```
Part 1. The case n = 2 and k is a field.
```

### 1.1. A preliminary step.

We begin with the following lemma.
Lemma 1.1. Let $\sigma \varepsilon$ Aut $_{k} k[x, y]$. If $\sigma x=c x+d$ with $c, d \varepsilon k$, then $\sigma \varepsilon J$.

Proof. oy is expressed as $\mathrm{yh}(\mathrm{x}, \mathrm{y})+\mathrm{f}(\mathrm{x})$, with $\mathrm{f}(\mathrm{x}) \varepsilon \mathrm{k}[\mathrm{x}]$, $h(x, y) \varepsilon k[x, y]$. Then $k[x, y]=k[x, y h(x, y)]$, therfore there is a $k$-automorphism of $k[x, y]$ which sends $y$ to $y h(x, y)$. Therefore $y h$ must be irreducible, and $h$ is a unit in $k[x, y]$. Thus $h \varepsilon k$, and we see that $\sigma \in J$. q. e. d.

Now we assert that in order to prove the generation of $A u t{ }_{k} k[\bar{x}, y]$ by $J=J(2, k)$ and $G=A(2, k)$, we have only to show the following (1.2) If $\sigma \varepsilon A_{\mathrm{A}}^{\mathrm{k}} \mathrm{k}[\mathrm{x}, \mathrm{y}]$, then there is an element $\tau$ in the group $J \vee_{G}$ generated by $J$ and $G$ such that $\sigma x=\tau x$. Because, if this statement is proved, then $\tau^{-1} \sigma$ is in $J$ by Lemma 1.1 and we see that $\sigma \varepsilon J^{\vee} G$.

Therefore we are going to prove (1.2) by induction on the degree $d$ of $\sigma x$. If $\mathrm{d}=1$, then the assertion is obvious and we assume that $\mathrm{d}>1$. We consider the projective plane $\mathbb{P}^{2}$ with generic point (tx, ty, $t$ ) $=(X, Y, Z)$ so that $Z \neq 0$ gives the affine plane $\Omega^{2}$ with coordinate ring $k[x, y]$. Then we consider the linear system $L$ defined by
$\{x+c \mid c \in k\}$, or more precisely, $L=\left\{C_{a} \mid a \varepsilon \Omega\right\} \cup\left\{d_{\ell_{\infty}}\right\}$ where $C_{a}$ is the plane curve defined by $h(X, Y, Z)+a Z^{d}$ with homogeneous form $h$ of degree $d$ such that $h(x, y, 1)=\sigma x$. Note that
(1.3) Coefficients of the defining equations for members of $L$ can be chosen to be independent of the member, except for the coefficient of $\mathrm{Z}^{\mathrm{d}}$ and also except for the member $\mathrm{d} \cdot \ell_{\infty}$.

Note also that
(1.4) $\sigma$ defines a birational correspondence $T: \mathbb{P}^{2} \rightarrow \mathbb{P}^{2}$ by $(x, y, 1) \longrightarrow(\sigma x, \sigma y, 1)$ and $T$ is biregular on $\Omega^{2}=T^{2}-\ell_{\infty}$ 。

L is then the effective transform of pencil of lines, on the first $\mathbb{P}^{2}$, going through $(0,1,0)$.

Obviously, $\Omega[x, y] /(\sigma x+a) \cong \Omega[t]$ with a variable $t$ over $\Omega$. Therefore (1.3) implies that $d \cdot \ell_{\infty}$ is the only reducible memebt of $L$ and that $C_{a} \cap^{2}$ is biregular to an affine line. Therefore there is only one ordinary point $P$ common to $C_{a}$ and $\ell_{\infty}$ and $P$ is a one-place point of $C_{a}$. Furthermore, if $a \neq a^{\prime}$, then $C_{a}$ and $C_{a}$, do not meet each other in $\Omega^{2}$. Therefore the point $P$ is common to all $C_{a}$. Thus we have
(1.5) There is an ordinary point $P$ on $l_{\infty}$ such that $P$ is a one-place point of all $C_{a}$ and $C_{a} \cdot \ell_{\infty}=d P$.

Consider one $C_{a}$ with $a \varepsilon k$. Then since $k[x, y] /(\sigma x+a) \cong k[t]$,
we have

$$
\left\{\begin{array}{l}
x \equiv c_{10}+c_{11} t+\ldots+c_{1 r} t^{r}  \tag{1.6}\\
y \equiv c_{20}+c_{21} t+\ldots+c_{2 s} t^{s}
\end{array} \quad(\bmod \sigma x+a)\right.
$$

where $c_{i j} \varepsilon k, \quad c_{1 r} c_{2 s} \neq 0$.

Since the degree $d$ is the number of intersections of $C_{a}$ and a Iine at a general position, we see that $d=\max \{r, s\}$. Then, using the transposition of $x, y$ (which is in $G$ ) if necessary, we may assume that $s=d$. Then using a linear transformation which fixes $y$ if $r=d$, we may assume that $r<d$. Then $r$ is the number of intersections of $C_{a} \cap \Omega^{2}$ with the line $x=$ constani, $C_{a}$ and the line $x=$ constant must meet at infinity with intersection multiplicity $d-r$. Since $C_{a}$ has only one point $P$ at infinity and since $P$ is a one-place point such that $C_{a} \cdot \ell_{\infty}=d P$, we see that $d-r$ must be the multiplicity of $P$ on $C_{a}$. Since $I$ is a linear system which is the effective transform of a pencil of lines, singularities of irreducible members of $L$ must be common to all irreducible members (Part 0, Remark 5.11). Therefore
(1.7) In (1.6), we may assume that $s=d>r$. These $r$ and $s$ are independent of the particular choice of a. Furthermore, $r=d-$ (multiplicity of $P$ on $C_{a}$ ).

Now we consider applications of elements of J . Let $1 \varepsilon \mathrm{~J}$. Then
the linear system $L^{\prime}$ to observe is the one defined by $\{1 \sigma x+a \mid a \varepsilon k\}$. Therefore ( 1.7 ) implies that if there is an $1 . \varepsilon \mathrm{J}$ such that the degree of $y$ in $t$ on the new $C_{a}$ become smaller than $d$, it implies that the degree of $1 \sigma x$ is less than $d$, hence we complete the proof by induction argument on $d$. Since the above reduction is possible if $d$ is a multiple of $r$, we have that
(1.8) Assume in (1.6) that $r<s=d \neq 1$. Then in order to prove that Aut $k[x, y]=J V_{G}$, it is enough to show that $d$ is a multiple of $r=d-$ (the multiplicity of $P$ on $C_{a}$ ).

We are to give two proofs of (1.8): one is geometric (§ 1.2) and the other is rather due to computation of numericals (3 1.3).
1.2. Geometric proof of (1.8).

We shall make use of some results on rational ruled surfaces. Though we shall refer them to [7] for the detail, we sketch some of basic facts.

By a ruled surface, we mean a projective non-singular surface $V$ from which there is a regular map $T$ onto a curve $C$ such that inverse image of each point of $C$ is a non-singular rational curve, or, equivalently, there is a pencil $L$ of curves on $V$ having no fixed point and such that every member of $L$ is biregular to $\mathbb{P}^{1}$. Each member of $L$ is called a fibre or a generator. An irreducible curve $C$ on $V$ is
called a section if the intersection number $(C, \ell)=1$ for a fibre $\ell$. A minimal section is a section whose self-intersection number is the smallest among sections. In the case of rational ruled surfaces, the product $\mathbb{P}^{1} \times \mathbb{P}^{1}$ of projective lines is one special example, because it has two ruled surface structures. We take one of its, so that $\mathbb{H}^{1} \times P \quad\left(P \varepsilon \mathbb{P}^{1}\right)$ are fibres and $Q \times \mathbb{P}^{1} \quad\left(Q \in \mathbb{P}^{1}\right)$ are minimal sections. Now, take one $Q \times \mathbb{P}^{1}$ and let $P_{1}, \ldots, P_{n}$ be mutually distinct ordinary points lying on the section $Q \times \mathbb{P}^{1}$. Then we can consider the elementary transformation $\quad \lim _{\mathrm{P}_{1}} \ldots \mathrm{P}_{\mathrm{n}}$ on $\mathbb{P}^{1} \times \mathbb{P}^{1}$, and we obtain a rational ruled surface.

Notation 2.1. A ruled surface which is biregular to
$\operatorname{lm}_{P_{1}} \ldots P_{n} \mathbb{F}^{1} \times \mathbb{P}^{1}$ is denoted by $F_{n}$ in general (including the case where $\mathrm{n}=0$, namely, $\mathbb{P}^{1} \times \mathbb{P}^{1}$ is an $\mathrm{F}_{0}$ ).

Of course, we must observe that the definition above does not depend on the particular choice of the points $P_{1}, \ldots, P_{n}$, namely two $\mathrm{F}_{\mathrm{n}}$ are biregular to each other. Furthermore,

Proposition 2.2. (i) A rational ruled surface is an $F_{n}$ for some $n$. Furthermore (ii) if $m \neq n$, then $F_{m}$ cannot be isomorphic to $F_{n}$. Actually, if $m>0$, then $F_{m}$ has only one minimal section, whose self-intersection number is $-m$.

Proposition 2.3. Let $P$ be an ordinary point on an $F_{n}$.
(i) If P lies on a minimal section, then $e 1_{\mathrm{P}_{\mathrm{P}}} \mathrm{F}_{\mathrm{n}}$ is an $\mathrm{F}_{\mathrm{n}+1}$.
(ii) Otherwise, $e \operatorname{lm}_{\mathrm{P}} \mathrm{F}_{\mathrm{n}}$ is an $\mathrm{F}_{\mathrm{n}-1}$.

As for the relationship with $\mathbb{P}^{2}$, Proposition 2.4. If $P$ is an ordinary point of $\mathbb{P}^{2}$, then di1 $P_{P} \mathbb{P}^{2}$ is an $F_{1}$. Fibres are proper transforms of lines going through $P$ and the minimal section is $\mathrm{dil}_{\mathrm{P}} \mathrm{P}$.

One preliminary result we need is

Proposition 2.5. Let $V$ be an $F_{n}$, \& a fibre, $b$ a section and let $P$ be the common point of $l$ and $b$. Assume that a curve $C$ on $V$ goes through $P$ and $P$ is a one-place point of $C$. Furthermore, assume that $C \cdot \ell=\alpha P, C \cdot b=\beta P$ with natural numbers $\alpha$ and $\beta$. Let $W=$ elm $V$, let $C^{\prime}, b^{\prime}$ be proper transforms of $C, b$ on $W$, let $P^{\prime}$ be the point on $W$ corresponding to $l, l$ " the fibre corresponding to $P$ and let $Q^{\prime}$ be the infinitely near point to $P$ of order one lying on $b$ (hence is the common point of $\ell^{\prime}$ and $b^{\prime}$ ). Then
(1) if $\beta>\alpha$, then $C^{\prime} \cdot b^{\prime}=(\beta-\alpha) Q^{\prime}, C^{\prime} \cdot \ell^{\prime}=\alpha Q^{\prime}$,
(2) if $\beta<\alpha$, then $C^{\prime} \cdot \ell^{\prime}=\alpha P^{\prime}$,
(3) if $\beta=\alpha$, then $C^{\prime}$ do not go through any of $P^{\prime}, Q^{\prime}$.

In any case, the ordinary point where $C^{\prime}$ meets $\ell^{\prime}$ is a one-place point of $C^{\prime} . \quad m=\min \{\alpha, \beta\}$ is the multiplicity of $P$ on $C$.

Proof. Denoting by $C^{\prime \prime}, \ell^{\prime \prime}, b^{\prime \prime}$ the proper transforms of
$C$, l, b, respectively, on $d i l_{P} V$, we see that $\left(C^{\prime \prime}, d i 1_{P} P\right)=m$ and therefore $\left(C^{\prime \prime}, b^{\prime \prime}\right)=(C, b)-m,\left(C^{\prime \prime}, \ell^{\prime \prime}\right)=(C, \ell)-m$. From this, we see (1), (2), (3) immediately. The last assertion is immediate from the property of a one-place point. q. e. d.

Before going back to (1.8), we give a remark on fundamental points of the birational correspondence $T: \mathbb{P}^{2} \longrightarrow \mathbb{P}^{2}$ given by $(x, y, 1) \longrightarrow(\sigma x, \sigma y, 1) . \quad$ For distinction of these projective planes, we denote them by $V$ and $W$ so that $T: V \longrightarrow W$. Assume on the other hand that $T$ is not biregular. Let $L *$ be the linear system of lines on $W$ and let $L * *$ be the effective transform $T_{\text {ef }}^{-1} L *$. Since $T$ is biregular on $\Omega^{2}=\mathrm{V}-\ell_{\infty}$, for each irreducible member C of $\mathrm{L} * *$, its affine part $C \cap \Omega^{2}$ is biregular to an affine line. Therefore there is one and only one common ordinary point, say $P$, of $C$ and $\ell_{\infty}$ and $P$ is a one-place point of $C$. Note that fixed points of $L^{*} *$ amounts the same as fundamental points with respect to $T$. Since $L^{* *}$ has no fixed point on $\Omega^{2}, P$ must be the unique fixed point among ordinary points. In view of the fact that $P$ is a one-place point, we have Proposition 2.6. All of fundamental points with respect to $T$ form a sequence, say, $P=P_{0}, P_{1}, \ldots, P_{s}$ such that each $P_{i} \quad(i>0)$ is an infinitely near point to $P_{i-1}$ of order one.

```
Proof of (1.8). If r = 1, or if T defined above is a biregular
```

map, then $d=1$ and therefore we assume that $r>1$ and $T$ is not biregular. Let $L$ be as in $\S 1.1$, and we consider fixed points of $L$. By the same reason as above, they form a sequence $P_{0}^{\prime}, P_{1}^{\prime}, \ldots, P_{\gamma}^{\prime}$ so that each $P_{i}(i>0)$ is an infinitely near point of order one to $P_{i-1}$. Since an irreducible member $C$ of $L$ is rational and of degree $d>1$, C must have at least one singular point. Hence, by virtue of Part 0, Remark 5.11 $P_{0}^{\prime}$ (even if $\gamma=0$ ) and also all $P_{i}^{\prime}$ for $i<\gamma$ must be fundamental with respect to $T$. Therefore Proposition 2.6 shows that $P_{0}^{\prime}=P$ and for $i<\gamma, P_{i}^{\prime}=P_{i}$. We consider $d i 1_{P} V$. This is an $F_{1}$ with unique minimal section dil $_{P} P$ which we shall denote by $b_{1}$. Note that $V$ is the unique $\mathbb{T}^{2}$ birationally dominated by this $F_{1}$. Therefore we have

$$
\begin{equation*}
s \geq 1 \tag{2.7}
\end{equation*}
$$

Starting with this $F_{1}$, we consider sequence of $F_{1}, \ln _{P_{1}} F_{1}$, $\ldots, \operatorname{lm}_{P_{1}} \ldots P_{\alpha} F_{1}$ as far as $P_{1}, \ldots, P_{\alpha}$ lie on $b_{1}$ (for the definition of the term " lie on ", see § 0.5, p.15). Because of the condition, each $V_{\alpha+1}=\operatorname{elm}_{P_{1}} \ldots P_{\alpha} F_{1}$ is an $F_{\alpha+1}$ (the original $\mathrm{F}_{1}=\mathrm{dil}_{\mathrm{P}} \mathrm{V}$ being $\left.\mathrm{V}_{1}\right) \cdot \mathrm{V}_{\beta}(\beta \leq \alpha+1)$ has a special fibre $\ell_{\beta}$ such that $\ell_{1}$ came from $\ell_{\infty}$ and $\ell_{\beta}(\beta>1)$ came from $P_{\beta-1}$. Let $b_{\beta}$ be the minimal section of $V_{\beta}$. Note that $b_{\beta}$ is the proper
transform of $b_{1}$. Let $C_{\beta}$ be the proper transform of $C$ on $V_{\beta}$. Since $P$ is a one-place point of $C$, we see that
(2.8) (i) $P_{\beta}$ is the unique common point of $b_{\beta}$ and $\ell_{\beta}$.
(ii) $\ell_{\beta}$ and $C_{\beta}$ have only one ordinary point, say $P_{\beta}^{\prime}$, in common.
(iii) If $b_{\beta}$ meets $C_{\beta}$, then $P_{\beta}^{\prime}=P_{\beta}$.

Set $m=d-r . m$ is the multiplicity of $P$ on $C$ by (1.7).
Therefore $\left(C_{1}, b_{1}\right)=m$ by Part 0 , Provosition 5.4 , hence we have $\left(C_{1}, l_{1}\right)$
$=\mathrm{d}-\mathrm{m}=\mathrm{r}$. Let q and $\mathrm{r}^{\prime}$ be non-negative integers such that
$m=q r+r^{\prime}, r^{\prime}<r$. If $m$ is a multiple of $r$, then $d$ is a multiple
of $r$. Therefore we assume that
(2.9) m is not a multiple of r , i.e., $\mathrm{r}^{\prime} \neq 0$.

We want to show that
(2.10) $\alpha \geq q$.

Assume that $q>\alpha .\left(C_{1}, l_{1}\right)=r<m=\left(C_{1}, b_{1}\right)$ implies that $P_{1}$ is an $r$-ple point of $C_{1}$. Then, on $V_{2}$, we have $\left(C_{2}, l_{2}\right)=r$, $\left(C_{2}, b_{2}\right)=m-r$. Thus, step by step, by virtue of our assumption that $q>\alpha$, we see that $\left(C_{\alpha+1}, b_{\alpha+1}\right)=m-\alpha r>r=\left(C_{\alpha+1}, \ell_{\alpha+1}\right)$, and $P_{\alpha+1}^{\prime}$ is an r-ple point of $C$ and lies on $b_{1}$. By Part 0 , Remark 5.11, $P_{\alpha+1}^{\prime}$ is fundamental with respect to $W$ and therefore $P_{\alpha+1}^{\prime}=P_{\alpha+1}$. Thus (2.10) is proved.

By the same computation as above, we see that
(2.11) $\quad\left(\mathrm{C}_{\mathrm{q}+1}, \ell_{\mathrm{q}+1}\right)=r, \quad\left(\mathrm{C}_{\mathrm{q}+1}, \mathrm{~b}_{\mathrm{q}+1}\right)=m-\mathrm{qr}=\mathrm{r}^{\prime}>0$.

Let $Q$ be the common point of $l_{q+1}$ and $b_{q+1}$. (2.11) shows that $r^{\prime}$ is the multiplicity of $Q$ on $C$, and this is independent of the choice of the irreducible member $C$ of $L$. Hence $Q$ is a fixed point of $L$. Consider $\mathrm{dil}_{\mathrm{Q}} \mathrm{V}_{\mathrm{q}+1}$, and let $\mathrm{b}^{\prime}, \ell^{\prime}, C^{\prime}$ be the proper transforms of $b_{1} \quad\left(\right.$ or, $b_{q+1}$ ), $\ell_{q+1}, C$ (or, $C_{q+1}$ ) respectively. Since $r$ is the multiplicity of $Q$ on $C_{q+1}$, we have $\left(d_{Q} Q, C^{\eta}\right)=r^{p},\left(C^{\eta}, \ell^{\eta}\right)=$ $r-r^{\eta}>0$. Thus the common point, say $Q^{p}$, of dil $Q Q^{\prime}$ and $Q^{\prime}$ is a point lying on $C^{\prime}$. Thus $Q^{\prime}$ is also a fixed point of L. Hence we have by virtue of Part 0, Remark 5.11 that
(2.11) $Q$ is fundamental with respect to $W$, hence $Q=P_{q+1}$; $Q^{\prime}$ is either $P_{q+2}$ or the point $(0,1,0)$ of $W_{0}$ On $\operatorname{dil}_{Q} V_{q+1}$, irreducible curves such that (i) self-intersection numbers are ne, ative and (ii) lies completely out side of $\Omega^{2}$ are $b^{\prime}, l^{\prime}$ and dil $Q$ only. Therefore on $\operatorname{dil}_{P_{q+1}} \ldots P_{S} V_{q+1}$, those irreducible curves having selfintersection number -1 and lying completely outside of $\Omega^{2}$ are only some curves of the form $d i l_{P_{i}} P_{i}$. therefore, in order to obtain $W$ by successive contractions of irreducible exceptional curves of the first kind, we must contrant some of ${ }^{\operatorname{di}} \mathrm{P}_{\mathrm{P}} \mathrm{P}_{\mathrm{i}}$, which contradicts the assumption that $\mathrm{P}_{\mathrm{i}}$ is fundamental.

Thus $r^{\prime}$ cannot be positive, and we complete the proof of (1.8).
1.3. Remarks to the proof.

Let us look at the proof of the last section again. The first place we should change now is (2.9), where $r^{\prime}$ was assumed to be positive, but we know now that $r^{\prime}=0$. (2.10) is still good and (2.11) becomes
(3.11) $\quad\left(C_{q+1}, \ell_{q+1}\right)=r, \quad\left(C_{q+1}, b_{q+1}\right)=0$.

Since $L$ is the effective transform of a complete linear system with a base condition, $L$ itself must be a complete linear system with a certain base condition. On the other hand, members of $L$ are of degree $d=m+r$ ( $r$ is assumed to be at least 2) and $P_{0}$ is an $m$-ple point, $P_{1}, \ldots, P_{q+1}$ are $r-p l e$ points. Let $L_{d}$ be the linear system of curves of degree $d$ on $V$, then we see, by virtue of the fact that $\mathrm{m}=\mathrm{qr}$, that

$$
\begin{aligned}
& \operatorname{dim}\left[L_{d}-\left(m P_{0}+\sum_{i=1}^{q} r P_{i}\right)\right] \geqq \frac{1}{2}\left[d^{2}+3 d-m(m+1)-q r(r+1)\right] \\
& =-\frac{1}{2}\left[m^{2}+r^{2}+2 m r+3 m+3 r-m^{2}-m-m r-m\right] \\
& =\frac{1}{2}\left[r^{2}+m r+m+3 r\right]=\frac{1}{2}(d r+d+2 r)>d+r \geq d+2
\end{aligned}
$$

But, $\operatorname{dim} L=1$, hence $L$ must have either at least one more singular fixed point or at least two more fixed point. Therefore, by virtue of

Remark 5.11 in Part 0, $P_{q+1}$ is a fixed point of $L$. If $P_{q+1}$ iies on $\ell_{q}$, then $P_{q+1}$ must be the common point of $\operatorname{diI}_{P_{q}} P_{q}$ and the proper transform of ${ }^{\ell_{q}}$ on $\mathrm{dil}_{\mathrm{P}_{\mathrm{q}}} \mathrm{V}_{\mathrm{a}}$. Then, by the same argument as at the end of the last section, we have a contradiction. Hence $P_{q+1}$ is an ordinary point of $\ell_{q+1}$. Since $\left(C_{q+1}, b_{q+1}\right)=0$, we see that $P_{q+1} \notin b_{q+1}$. Thus $P_{q+1}$ is an ordinary point of ${ }^{\ell}{ }_{q+1}$ and is neither the common point of $\ell_{q+1}$ and $b_{q+1}$ nor the point which is the proper transform of ${ }_{q}{ }_{q}$ Now we consider the sequence $W_{0}=V_{q+1}, W_{1}=e \operatorname{lm}_{p_{q+1}} W_{0}, \ldots, W_{B}=$ $\operatorname{elm}_{q+\beta} W_{\beta-1}$, as far as possible but with restriction that $\beta \leq q$. Let $\ell^{\prime}$ be the fibre on $W_{i}$ corresponding to $P_{q+i}$ and let $b_{i}$ be the minimal section of $W_{i}$. Note that the common point of $l_{i}^{i}$ and $b_{i}^{?}$ is the proper transform of $l_{i-1}^{i}$. By this fact and by the same argument as at the end of the last section, we see that if $q+i+1 \leq s$, then $P_{q+i+1}$ is an ordinary point lying on $\ell_{i}^{?}$ which is not the common point of $l_{i}^{\prime}$ and $b_{i}^{\prime}$. Therefore we see that $W_{i}$ is an $F_{q-i}$, hence $q+i+1 \geq s$ unless $i=q$. Therefore $\beta=q$ and $W_{q}$ is an $F_{1}$. $\mathrm{W}_{\mathrm{q}}$ dominates a $\mathbb{P}^{2}$, say $\mathrm{W}^{*}$. Let P * be the transform on $\mathrm{W}^{*}$ of the minimal section of $W_{q}$.

By the nature of the transform, we see that
(1) Either $W^{*}=W$ or $s>2 q$ and $P_{2 q+1}, \cdots, P_{s}$ are all of the fundamental points of $W^{*}$ with respect to $W$.
(2) The transformation $j=\operatorname{cont}_{b}^{\prime} \cdot{ }_{q}{ }^{1 m_{p_{1}}} \ldots P_{2 q} \cdot{ }^{d i 1_{p_{0}}}$ is induces by some element $\tau$ of $\operatorname{Aut}_{k} k[x, y]$.

We shall show now

Proposition 3.2. Above $j$ is a special type of Jonquieres transformation and $\tau$ is an element of $J=J(2, k)$ under suitable choice of coordinates systems on $V$ and $W^{*}$. Conversely, every element of $J$ is obtained in this manner.

Proof. We begin with the last assertion. Let $\tau$ be an element of J. The linear system $L^{*}$ corresponding to this birational transformation is defined by the module generated by $1, x, y+f(x)$ with $f(x) \varepsilon k[x]$. Therefore the module of defining homogeneous forms of members of $L *$ is generated by $Z^{q}, X Z^{q-1}$ and $Y^{q-1}+f *(X, Z)$, where $q=\operatorname{deg} f(x)$ and $f *$ is the form of degree $q$ such that $f *(x, 1)=f(x)$. Then one sees easily that $P=(0,1,0)$ is a $(q-1)-p l e$ point of members of $L^{*}$, hence $\tau$ is a Jonquières transformation. By a similar argument as we made above in this section, we see that the birational transformation defined by $\tau$ is of the form as $j$ above. This completes the proof of the last assertion. Let us prove the first assertion. We use the notation of $\S 1.2$. By virtue of the generation of $A u t_{k} k[x, y]$ by $G=A(2, k)$ and $J$, we see that the fundamental points $P=P_{0}, P_{1}, \ldots, P_{s}$ are all k-rational. On the other hand, we see that $j$ is a Jonquières
transformation such that the module of the corresponding linear system contains $Z^{q}$ and $X Z^{q-1}$. Indeed, because of the special position of the points $P_{1}, \ldots, P_{q}$ such that they lie on $d i l_{P} P$, we see easily that $\ell+(q-1) \ell_{\infty}$ goes through $(q-1) P+\sum_{i=1}^{2 q} P_{i}$ if $\ell$ is a curve going through $P$. Since $P, P_{1}, \ldots, P_{2 q}$ are all k-rational, we see that $j$ induces an element of $A u t{ }_{k} k[x, y]$. Since $Z^{q}$ and $X Z^{q-1}$ are in the module, we may assume that $x$ is invariant under the automorphism induced by $j$. Then, by Lemma 1.1 , we see that $j$ is in $J$. Thus the proof is completed.

We shall prove one more result:

Theorem 3.3. $\quad \operatorname{Aut}_{k} k[x, y]$ is so-called amalgamated product of $G=A(2, k)$ and $J=J(2, k)$. Namely, $\sigma_{i} \varepsilon G, \sigma_{i} \neq J, \tau_{i} \varepsilon J, \tau_{j} \notin G$ (i $=1,2, \ldots, n \geq 1$ ) imply that ${ }^{\tau} 1_{1}{ }_{1} \cdots{ }^{\tau}{ }_{n-1}{ }^{\sigma} n-1{ }^{\tau}{ }_{n} \& G$. (cf. [6])

Proof. Note that the set of elements of $G$ which fixes the point $(0,1,0)$ is exactly the subgroup $G \cap J$. Each element of $J$ which is not in $G$ defines a Jonquieres transformation having ( $0,1,0$ ) as the unique ordinary fundamental point and also having ( $0,1,0$ ) of the new plane as the unique ordinary fundamental point with respect to the inverse transformation. Therefore, if we look at the multiplication of ${ }^{\tau_{i}} \sigma_{i}$ to ${ }^{\tau}{ }_{i+1} \sigma_{i+1} \cdots \sigma_{n-1}{ }^{\tau}{ }_{n}$, we see that no fundamental points of these factors are cancelled out by the multiplication because $\sigma_{i}$ changes
$(0,1,0)$, hence the factor $\tau_{i}$ gives fundamental points which are infinitely near points to the last fundamental point with ${ }^{\tau}{ }_{i+1} \sigma_{i+1} \cdots \tau_{n}$. Thus the number of fundamental points with respect to ${ }^{\tau}{ }_{1} \sigma_{1} \cdots{ }_{n-1}{ }^{\tau}{ }^{n}$ is exactly the sum of the number of fundamental points with respect to $\tau_{i}(i=1, \ldots, n)$, hence the product cannot be in $G$. This completes the proof of Theorem 3.3.
1.4. Another proof.

We shall prove (1.8) in a stronger form. Namely

Theorem 4.1. Assume that $C$ is an irreducible rational curve of degree $d$ on $\mathbb{P}^{2}$ and that there is an ordinary point $P$ such that
(1) P is a one-place point of C ,
(2) $C \cdot \ell_{\infty}=d P$, and
(3) the affien part $C \cap \Omega^{2}$ is biregular to an affine line.

Let $P=P_{1}, P_{2}, \ldots, P_{n}$ be all the singularities of $C$ ( $P_{i}$ being an infinitely near point if $P_{i-1}$ for each $i=2, \ldots, n$ ) with respective multiplicities $m=m_{1}, m_{2}, \ldots, m_{n}$. Then either $d$ is a multiple of $d-m_{1}$ or $\sum m_{i}^{2}>d^{2}+3$.

In particular, if the linear system $L$ of curves of degree $d$ going through $\sum m_{i} p_{i}$ is of positive dimension, then $d-m_{1}$ divides $d$.

Before proving the theorem, we introduce a notion which we shall
call a (d, r)-sequence.

When two natural numbers $d$ and $r$ such that $d>r$ are given, the sequence $r_{1}, \ldots, r_{q}$ defined as follows is called the $(d, r)$ sequence :

Start with $d_{0}=d$ and $d_{1}=r$. When $d_{0}, \ldots, d_{j}$ are defined and if $d_{j}>0$, let $q_{i}$ and $d_{j+1}$ be such that $d_{j-1}=q_{j} d_{j}+d_{j+1}$ $\left(0 \leq d_{j+1}<d_{j}\right)$. Then for every $k$ such that $\left(\sum_{i<j} q_{i}\right)+1 \leq k$ $\leq \sum_{i<j} q_{i}, \quad r_{k}$ is defined to be $d_{j}$.

Lemma 4.2. Under the notation, we have

$$
\begin{aligned}
& q=\sum_{i=1}^{\alpha} q_{i}, \quad d_{\alpha}=G \cdot C \cdot M_{0}(d, r) \quad \text { and } \\
& \sum r_{i}=d+r-d_{\alpha}, \quad \sum r_{i}^{2}=d r .
\end{aligned}
$$

Prood. We have

$$
\begin{array}{cc}
d_{0}=q_{1} d_{1}+d_{2}: & d_{0} d_{1}=q_{1} d_{1}^{2}+d_{1} d_{2} \\
d_{1}=q_{2} d_{2}+d_{3} ; & d_{1} d_{2}=q_{2} d_{2}^{2}+d_{2} d_{3}, \\
\ldots \ldots & \ldots \\
\ldots \ldots & \\
d_{\alpha-2}=q_{\alpha-1} d_{\alpha-1}+d_{\alpha}: & d_{\alpha-2} d_{\alpha-1}=q_{\alpha-1} d_{\alpha-1}^{2}+d_{\alpha-1} d_{\alpha} \\
d_{\alpha-1}=q_{\alpha} d_{\alpha} ; & d_{\alpha-1} d_{\alpha}=q_{\alpha} d_{\alpha}^{2} .
\end{array}
$$

Summing up these equalities respectively, we have $d_{0}+d_{1}=$ $\Sigma q_{i} d_{i}+d_{\alpha} ; d_{0} d_{1}=\Sigma q_{i} d_{i}^{2}$ and we have the required result.

Proposition 4.3. Let $C$ be an irreducible curve on a non-singular surface $F$ and let $P$ be a one-place point of $C$. Let $m$ be the multiplicity of $P$ on $C$. Let $D$ be another irreducible curve on $F$ which goes through $P$ as a simple point. Let $d$ be the intersection multiplicity of $C$ with $D$ at $P$, and let $c$ be the G.C.M. ( $d, m$ ). Let the $(d, m)$-sequence be $r_{1}, \ldots, r_{q}$. Then there is a sequence of points $P_{1}=P, P_{2}, \ldots, P_{q}$ which is determined uniquely by $d / c, r / c$ and $D$ such that ( $i$ each $P_{i+1}$ is an infinitely near point of $P_{i}$ of order one and (ii) effective multiplicity of $P_{i}$ on $C$ is $r_{i}$. (The way of determination of $P_{i}$ is shown by the proof below.)

Proof. We use an induction argument on $d$. If $d=m$, then $q=1$, $r_{1}=m$ and the assertion is obvious. Assume that $d>m$. Consider the quadratic dilatation $d i I_{P} F$, the proper transforms $C^{\prime}, D^{\prime}$ of $C, D$ and also the intersection number $\left(\operatorname{dil}_{P} P, C^{\prime}\right)$. Since $P$ is an m-ple point of $C$, we have $\left(\mathrm{dil}_{\mathrm{P}} \mathrm{P}, \mathrm{C}^{\prime}\right)=\mathrm{m}$ by Proposition 5.4 in Part 0. Consider the unique common point $P_{2}$ of $\mathrm{dil}_{P} P$ and $D^{\prime}$. By our assumption on $P, P_{2}$ is the unique common ordinary point of $d i l_{P} P$ and $C^{\prime}$. On the other hand, since the intexsection multiplicity at $P$ of $C$ and $D$ is $d$ and since $P$ is m-ple on $C$, the intersection multiplicity
at $\mathrm{P}_{2}$ of C ' and $\mathrm{D}^{\prime}$ is $\mathrm{d}-\mathrm{m}$. Therefore the multiplicity of ' $\mathrm{P}_{2}$ on $C^{\prime}$ is the minimum of $m$ and $d-m$. Now, if $d-m>m$, then considering $C^{\prime}$ and $D^{\prime}$ instead of $C$ and $D$ respectively, we have a case with less $d$, and the proof is completed by our induction argument. On the other hand, if $m>d-m$, then considering $d i 1_{P} P$ and $C^{\prime \prime}$ instead of $D$ and $C$ respectively, we complete the proof similary. The following lemma is obvious.

Lemma 4.4. Let $m_{1}, \ldots, m_{n}$ be a sequence of natural numbers, such that $m_{1} \geq m_{2} \geq \cdots \geq m_{n}(\geq 1)$. Then for any $\alpha<n$

$$
\sum m_{i}^{2}<\sum_{i \neq \alpha, n} m_{i}^{2}+\left(m_{\alpha}+1\right)^{2}+\left(m_{n}-1\right)^{2}
$$

Corollary 4.5. Let $m_{1}, \ldots, m_{n}$ and $s_{1}, \ldots, s_{v}$ be positive integers, such that $\Sigma s_{i} \geq \Sigma m_{f}, m_{1} \geq \cdots \geq m_{n}$ and $s_{1} \geq \cdots \geq s_{V}$. If $s_{i} \geq m_{i}$ for $i=1, \ldots, v-1$, then

$$
\Sigma s_{i}^{2} \geq \sum m_{j}^{2}, \quad \sum s_{i}\left(s_{i}-1\right) \geq \Sigma m_{j}\left(m_{j}-1\right)
$$

Now we are going to prove Theorem 4.1.

Consider $C, d, m_{i}, P_{i}$ and so on as in the theorem. Let $\left(d, m_{1}\right)$ sequence be $m_{1}=r_{1}, r_{2}, \ldots, r_{q}$.
(1) Assume that G.C.M. $(\mathrm{d}, \mathrm{m})=1$. Then we see by virtue of

Proposition 4.3 that $m_{i}=r_{i}$ for any $i \leq n$ and $r_{n+1}=r_{n+1}=\ldots=$ $r_{q}=1$. This means that 2 (genus of $C$ ) $=d^{2}-3 d+2-\Sigma r_{i}^{2}+\Sigma r_{i}=$ $d\left(d-m_{1}-2\right)+m_{1}+1$ by Lemma 4.2. Therefore, by the fact that $C$ is rational, we have $d-m_{1}-2<0$, whence $m_{1} \geq d-1$, and we see that $m_{1}=d-1$, and therefore $1=d-m_{1}$ divides $d$ in this case.
(2) Assume now that $\delta=\left(d, m_{1}\right) \neq 1$ and that $d-m_{1}$ does not divide $d$. Then $n \geq q$ and $m_{i}=r_{i}$ for any $i \leq q$ and $m_{j} \leq \delta$ for any $j>q$. On the other hand,

$$
\begin{aligned}
0 & =2 \text { (genus of } C \text { ) }=d^{2}-3 d+2-\sum m_{i}^{2}+\sum m_{i} \\
& =d^{2}-3 d+2-\sum_{i<q} m_{i}^{2}+\sum_{i \leq q} m_{i}-\sum_{j>q} m_{j}^{2}+\sum_{j>q} m_{j} \\
& =d\left(d-m_{1}\right)-2 d+m_{1}+2-\delta-\sum_{j>q} m_{j}^{2}+\underset{j>q}{\sum} m_{j} .
\end{aligned}
$$

Let the $\left(d, d-m_{1}\right)$-sequence be $s_{1}, \ldots, s_{q}$. Then $\sum s_{i}^{2}=d\left(d-m_{1}\right)$, $\Sigma s_{i}=d+\left(d-m_{1}\right)-\delta$. Therefore

$$
\begin{equation*}
\underset{j>q}{\sum} m_{j}^{2}-\underset{j>q}{\sum} m_{j}=\Sigma s_{i}^{2}-\Sigma s_{i}+2-2 \delta . \tag{4.6}
\end{equation*}
$$

Since $d-m_{1}$ does not divide $d, d-m_{1}$ is a proper multiple of $\delta ; d-m_{1}=u \delta(u \geq 2)$. On the other hand, let $\beta$ and $\gamma$ be integers such that $\sum_{j>q} m_{j}=\beta \delta+\gamma, 0<\gamma<\delta$. Set $\delta_{1}=\ldots=\delta_{\beta}=\delta$, $\delta_{\beta+1}=\gamma$. Then $\Sigma \delta_{i}=\Sigma_{j>q} m_{j}$ and, by Corollary 4.5, and by the fact
that $\mathrm{m}_{\mathrm{i}} \leq \delta$

$$
\sum \delta_{i}^{2}-\sum \delta{ }_{i} \geq \sum_{j>q} m_{j}^{2}-\sum_{j>q} m_{j}
$$

Assume for a moment that $\sum_{j>q} m_{j} \leq \Sigma s_{i}+2 \delta$. Then, since $s_{i} \geq \delta$, we have similarly

$$
\sum_{i>2} s_{i}^{2}-\sum_{i>2} s_{i} \geq \sum_{i>u+2} \delta_{i}^{2}-\sum_{i>u+2} \delta_{i} .
$$

Therefore

$$
\begin{aligned}
\Sigma s_{i}^{2}-\Sigma s_{i} & \geq s_{i}^{2}-s_{1}+\sum_{i>u+2}^{\sum} \delta_{i}^{2}-\sum_{i>u+2} \delta_{i} \\
& =u^{2} \delta^{2}-u \delta+\sum_{i>u+2}^{\sum} \delta_{i}^{2}-\sum_{i>u+2} \delta_{i} \\
& =\left(u^{2}-u-2\right) \delta^{2}+2 \delta+\sum \delta_{i}^{2}-\Sigma \delta_{i} \\
& \geq 2 \delta+\sum_{j>q} m_{j}^{2}-\sum_{j>q} m_{j} \\
& =2 \delta+\sum s_{i}^{2}-\sum s_{i}+2-2 \delta
\end{aligned}
$$

This implies $2 \leq 0$, which is impossible. Therefore we must have

$$
\sum_{j>q} m_{j}>\Sigma s_{i}+2 \delta
$$

Then, since $\sum_{i \leq q} m_{i}+\Sigma s_{i}=d+m_{1}-\delta+d+\left(d-m_{1}\right)-\delta=3 d-2 \delta$
(by Lemma 4.2), we have

$$
\sum m_{i}>3 d
$$

Since $0=d^{2}-3 d+2-\Sigma m_{i}^{2}+\Sigma m_{i}$, we have $\Sigma m_{i}^{2}=d^{2}-3 d+2+\Sigma m_{i}$ $>d^{2}+2$. This proves the main part of Theorem 4.1. As for $L$, this implies that two members of $L$ have intersection number bigger than $d^{2}+2$ which cannot happen unless they have common components. Since $L$ has an irreducible member $C$, we see that $\operatorname{dim} L=0$.

By these (1) and (2), we completes the proof of the Theorem 4.1.
1.5. One question on rational curves.

As we stated in Part 0 as Conjecture 1.1, it has been questioned that when $C$ is a rational curve in $\mathbb{P}^{2}$ of degree $d$ such that (i) there is only one ordinary point $P$ which is common to $C$ and $\ell_{\infty},(i i) \quad C-\{P\} \quad$ (i.e., $C \cap \Omega^{2}$ ) is biregular to an affine line, then whether or not $d$ is a multiple of $d$ (the multiplicity of $P$ on $C$ ).

In the characteristic $p \neq 0$ case, one have a counter-example as we shall see later in this section.

On the other hand, Abhyankar and Moh [1] proved affirmatively the question in the classical case (i.e., in the case of ground field of characteristic zero), and also the following : If $d$ is not a multiple of the characteristic of the ground field, then $d$ is a multiple of d - (the multiplicity of $P$ on $C$ ).

Note that if this conjecture is affirmative, then one can see easily by induction on $d$ that such a $C$ (with $d$ not multiple of the characteristic of the ground field $k$ ) is defined by an $f(x, y) \varepsilon k[x, y]$, for which there is an element $\sigma \varepsilon \operatorname{Aut}_{k} k[x, y]$ so that $\sigma x=f(x, y)$. Now we shall give a family of proposed counter-examples. Assume that the ground field $k$ is of characteristic $p \neq 0$. For each $b \varepsilon k$, let $C_{b}$ be the curve on $\Omega^{2}$ defined by the following representation by a parameter $t$ :

$$
\begin{align*}
& x=t^{p^{2}}  \tag{5.1}\\
& y=t^{\alpha p}+t+b
\end{align*}
$$

where $\alpha$ is a fixed natural number, $>1$ and prime to $p$.

One sees quite easily that

$$
k\left[t^{p^{2}}, t^{\alpha p}+t+b\right]=k[t]
$$

Therefore $C_{b}$ is biregular to an affine line. Let $C_{b}$ be the completion of $C_{b}$ in $\mathbb{P}^{2}$. Then $\left\{C_{b}^{\prime} \mid b \in k\right\}$ spans a pencil $L$ of curves of degree $d=\max \left\{p^{2}, \alpha p\right\}$. Every $C_{b}^{\prime}$ satisfies the conditions (i) and (ii) above with $P=(1,0,0)$ or $(0,1,0)$ according to $p>\alpha$ or $p<\alpha$. But the multiplicity of $P$ on $C_{b}^{\prime}$ is the difference of $p^{2}$ and $\alpha p$
hence every $C_{b}^{\prime}$ is a counter-example which we required. We give one more remark :

Proposition 5.2. The linear system $L$ has variable singularities among infinitely near points.

Proof is immediate from Theorem 4.1.

Part 2 Questions in the general case.

### 2.1 An example.

In Part 1, we observed the case of a polynomial ring of two variables over a field. As we discussed in Part 0, these results can be generalized easily to the case of a polynomial ring of two variables over an Artin ring.

But, if we deal with a more general case, we shall meet with many difficulties. In this Part 2, we shall discuss some of such difficulties.

Let us begin with an example.

Let $K$ be a field and consider the polynomial ring $R=K[x, y, z]$ of three variables. Set $k=K[z]$. Then $R$ is a polynomial ring of two variables $x, y$ over $k$. We are going to define an element $\sigma$ of Aut $\mathrm{k}_{\mathrm{k}} \mathrm{R}$ by:

$$
\left\{\begin{array}{l}
\sigma x=x-2 y\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2}  \tag{1.1}\\
\sigma y=y+z\left(z x+y^{2}\right)
\end{array}\right.
$$

It is obvious that (1.1) defines a k-homomorphism $\sigma: R \quad \mathrm{R}$. It is also obvious that $\sigma$ is an injection. As for this $\sigma$, we have

$$
\begin{align*}
\sigma\left(z x+y^{2}\right) & =z x+y^{2}  \tag{1.2}\\
\text { Indeed, } \sigma\left(z x+y^{2}\right) & =z\left(x-2 y\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2}\right)+\left(y+z\left(z x+y^{2}\right)\right)^{2} \\
& =z x+y^{2}
\end{align*}
$$

Let $\tau$ be a k-injection $R \longrightarrow R$ defined by
(1.3) $\left\{\begin{array}{l}\tau x=x+2 y\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2} \\ \tau y=y-z\left(z x+y^{2}\right) .\end{array}\right.$

Then, by virtue of (1.2), we have

$$
\begin{aligned}
\sigma \tau x & =\sigma\left(x+2 y\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2}\right) \\
& =x-2 y\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2}+2\left(y+z\left(z x+y^{2}\right)\right)\left(z x+y^{2}\right)-z\left(z x+y^{2}\right)^{2} \\
& =x \\
\sigma \tau y & =\sigma\left(y-z\left(z x+y^{2}\right)\right)=y+z\left(z x+y^{2}\right)-z\left(z x+y^{2}\right) \\
& =y
\end{aligned}
$$

Thus $\sigma \tau=1$. Since $\sigma$ and $\tau$ are injective, we see that $\sigma$ is an automorphism and that $\tau=\sigma^{-1}$. Now we assert :

Theorem 1.4. The automorphism $\sigma$ defined above is not in the group $J(2, k) \vee A(2, k)$.

Proof. Let $k^{*}$ be the field of quotients of $k$. Then $\sigma$, as an element of Aut $k_{k} k *[x, y]$, is equal to $\sigma_{1} \sigma_{2} \sigma_{1}^{-1}$, where

$$
\begin{aligned}
& \sigma_{1}\binom{x}{y}=\binom{x+z^{-1} y^{2}}{y}, \quad \sigma_{1}^{-1}\binom{x}{y}=\binom{x-z^{-1} y^{2}}{y}, \\
& \sigma_{2}\binom{x}{y}=\binom{x}{y+z^{2} x} .
\end{aligned}
$$

Note that $\sigma_{1} \varepsilon J\left(2, k^{\star}\right)$ and that $\pi \sigma_{2} \pi \varepsilon J(2, k)$ with $\pi \varepsilon \operatorname{SL}(2, k)$ such that $\pi x=y, \pi y=x$. Assume that $\sigma \varepsilon J(2, k) \vee A(2, k)$, i.e., there are $\tau_{i} \varepsilon J(2, k), \lambda_{i} \in A(2, k)$ such that

$$
\left\{\begin{array}{l}
0=\lambda_{1} \tau_{1} \lambda_{2} \cdots \tau_{2} \lambda_{n+1} \\
\tau_{i} \not \equiv A(2, k) \text { for every } i, \\
\lambda_{i} \notin J(2, k) \text { unless } \lambda_{i}=1, i=1 \text { or } n+1 .
\end{array}\right.
$$

Then we have

$$
\lambda_{1} \tau_{1} \lambda_{2} \ldots \tau_{n} \lambda_{n+1} \sigma_{1} \pi \sigma_{2} \pi \sigma_{1}^{-1}=1
$$

By the uniqueness of the factorization proved at Part 1, Theorem 3.3, we see that $\lambda_{n+1}=1$ and ${ }^{\top}{ }_{\mathrm{n}}{ }^{\sigma} 1 \varepsilon \mathrm{~A}(2, \mathrm{k} *)$. We write

$$
\left\{\begin{array}{l}
\tau_{n} x=a_{1} x+f(y) \\
\tau_{n} y=a_{2} y
\end{array}\right.
$$

Then $\tau_{n} \sigma_{1} x=a_{1} x+f(y)+z^{-1} a_{2}^{2} y^{2}$. Since $\tau_{n} \varepsilon J(2, k), a_{1}$ and $a_{2}$ are units in $k$ and $f(y) \varepsilon k[y]$. Therefore $f(y)$ has no term to cancell out the term $z^{-1} a_{2}^{2} y^{2}$. Hence $\tau_{n} \sigma_{1} x$ cannot be of degree $\leq 1$ in $y$. Thus ${ }^{\tau}{ }_{\mathrm{n}} \sigma_{1} \not \& \mathrm{~A}\left(2, \mathrm{k}^{*}\right)$. q. e. d.
$k$ in the above example is a polynomial ring in one variable over a field, hence is an Euclid ring. Thus our example shows that even if the coefficient ring $k$ is so good as an Euclid ring and $n=2$, the group Aut ${ }_{k} k[x, y]$ is not generated by $J(2, k)$ and $A(2, k)$ (cf. Exercise 1.6 below). Therefore we ask :

Question 1.5. Find a good structure theorem for $\operatorname{Aut}_{k} k[x, y]$ in the case where $k=K[z], K$ a field and $x, y, z$ a1gebraically independent over $k$, or more generally in the case where $k$ is reasonably good integral domain and $x$, $y$ algebraically in dependent over $k$.

Excercise 1.6. Let $k$ be an integral domain with a non-unit $z$. Take $\sigma \varepsilon$ Aut $_{\mathrm{k}} \mathrm{k}[\mathrm{x}, \mathrm{y}]$ defined by the same equality as (1.1). Prove that $\sigma$ is not in $J(2, k) \vee A(2, k)$.

### 2.2 Another example.

In § 2.1, we gave an example of $\sigma \in$ Aut $_{k} k[x, y]$ which is not in $J(2, k) \vee A(2, k)$. Letting $k *$ be the field of quotients of $k$, the example $\sigma$ as an element of $A_{i u t}{ }_{k *} \mathrm{k}^{*}[\mathrm{x}, \mathrm{y}]$ is the product of three automorphisms each of which induces a Jonquieres transformation of $\mathbb{P}^{2}$.

If we condsider worse $k$, then we have much simpler example, and we have the following

Theorem 2.1. Assume that $k$ is an integral domain which is not a principal ideal ring. Then there is an element $\sigma$ of $A_{k} k[x, y]$ ( $x, y$ being algebraically independent elements over $k$ ) such that
(i) $\sigma$ is not in $J(2, k) \vee A(2, k)$, and
(ii) $\sigma$ induces a Jonquières transformation of $\mathbb{P}^{2}$ over the field of quotients $k^{*}$ of $k$ 。

Let us construct a required example.

Let $a, b$ be elements of $k$ such that $a k+b k$ is not a principal ideal : such pair exists because of our assumption on $k$. Let $f(X)$ be a polynomial in one variable $X$ with coefficients in $k$. Let $\sigma$ be the $k$-homomorphism $k[x, y] \rightarrow k[x, y]$ defined by
$(2.2) \quad\left\{\begin{array}{l}\sigma x=x-b f(a x+b y) \\ \sigma y=y+a f(a x+b y)\end{array}\right.$

We are going to prove that this $\sigma$ is the example.

Consider k-homomorphism $\tau$ defined by
(2.3) $\quad\left\{\begin{array}{l}\tau x=x+b f(a x+b y) \\ \tau y=y-a f(a x+b y) .\end{array}\right.$

Then we have

$$
\begin{equation*}
\tau(a x+b y)=a x+b y \tag{2.4}
\end{equation*}
$$

Indeed, $t(a x+b y)=a(x+b f(a x+b y))+b(y-a f(a x+b y))$

$$
=a x+b y
$$

Therefore we see that

$$
\tau \sigma x=\tau(x-b f(a x+b y))=x+b f(a x+b y)-b f(a x+b y)=x,
$$

and similarly, we have $\tau \sigma y=y$. Thus we see that $\sigma$ is an element of Aut $k[x, y]$ and that $\tau=\sigma^{-1}$.

Since $\sigma(a x+b y)=a x+b y$, we see by virtue of Lema i.i in Part 1 that $\sigma$ induces a Jonquieres transformation of $\mathbb{P}^{2}$ over $k *$.

Now let us prove that $\sigma$ is not in $J(2, k) \vee A(2, k)$. Since $\sigma$ induces a Jonquieres transformation over $k *$, we see by virtue of Theorem 3.3 that if $\sigma$ is in $J(2, k) \vee A(2, k)$ then $\sigma=\lambda^{\prime} \sigma^{\prime} \lambda$ with $\sigma^{\prime} \varepsilon J(2, k), \lambda, \lambda^{\prime} \varepsilon A(2, k) .(2.4)$ shows that a polynomial $g(x, y)$ of degree $\leq 1$ is mapped to one of degree $\leq 1$ by $\sigma$ if and only if $g$ is of the form $d(a x+b y)+c(c \varepsilon k: d \varepsilon k *) . \lambda^{-1} y$ is such a polynomial. This means that by the linear automorphism $\lambda^{-1}, y$ is mapped to $d(a x+b y)+c(d a, d b, c \varepsilon k)$. Since $a k+b k$ is not $a$ principal ideal, we see that $d a k+d b k$ is not equal to the unit ideal $k$.

Hence, modulo a maximal ideal $m$ of $k$ containing $d a k+d b k$, we have that $\lambda^{-1} y$ is congruent to an element of $k$, and $\lambda^{-1}$ is not an element of $A u t_{k} k[x, y]$. Thus we obtained a contradiction, and therefore $\sigma \notin J(2, k) \vee A(2, k)$.
q. e. d.
2.3 The case of three or more variables.

Consider the case where $n=3$ and $k$ is a field. I am quite certain that $A_{k} k[x] \neq J(3, k) \vee A(3, k)(=J(3, k) \vee G L(3, k))$. Actually, look at the automorphism o defined in § 2.1. This is an element of $A u t_{K} K[x, y, z], K$ being a field.

Conjecture 3.1. This $\sigma$ is not in $J(3, K) \vee A(3, K)$.

I do not have any rigorous proof of this conjecture yet. But I have some reasoning for this, and $I$ am going to explain it later. (Theorem 1.4 in § 2.1 is a part of it.)

One important fact used in Part 1 is that, in the case of non-singular surfaces, birational transformations are very well described by fundamental points with help of the notion of infinitely near points. But, in the case of three dimensional non-singular varieties, we do not have satisfactory theory of infinitely near points ; relationship between monoidal dilatations whose centers have common points is complicated and therefore description of a birational transformation making use of monoidal transformations with nice centers is difficult.

Let us look at elements of $J(3, k) \vee A(3, k)$, or more generally, those of $J(n, k) \vee A(n, k)$ with $n \geq 3$; let us assume that $k$ is a field. In order to look at fundamental points of induced birational correspondences, it may be better to look at a smaller group $J *(n, k)$ defined by
(3.2) $J *(n, k)=\left\{\sigma \varepsilon J(n, k) \mid \sigma x_{i}=x_{i}\right.$ for every $\left.i \geq 2\right\}$.

It is easy to see
Lemma 3.3. $J(n, k) \vee A(n, k)=J *(n, k) \vee A(n, k)=J *(n, k) \vee G L(n, k)$. Now, we take coordinates of $\mathbb{P}^{\mathbb{n}}$ so that $\tau \varepsilon A u t_{k} k[x]$ induces birational transformation given by $\left(x_{1}, \ldots, x_{n}, 1\right) \longrightarrow\left(x_{1}, \ldots, \tau x_{n}, 1\right)$. Let $\tau \varepsilon J *(n, k), \tau \notin A(n, k)$. Then

$$
\begin{equation*}
\tau x_{1}=a x_{1}+f\left(x_{2}, \ldots, x_{n}\right), \tau x_{i}=x_{i} \text { for } i \geq 2 \tag{3.4}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\tau^{-1} x_{1}=a^{-1}\left(x_{1}-f\left(x_{2}, \ldots, x_{n}\right)\right), \quad \tau^{-1} x_{i}=x_{i} \text { for } i \geq 2 \tag{3.5}
\end{equation*}
$$

Thus we have

Lemma 3.6. Under the birational correspondence induced by $\tau$, (i) the hyperplane at infinity of the first $\mathbb{P}^{\mathrm{n}}$ corresponds to the point $(1,0, \ldots, 0)$ of the latter $\mathbb{P}^{\mathrm{n}}$ (as the proper transform),
(ii) the point $(1,0, \ldots, 0)$ of the first $\mathbb{P}^{\mathrm{n}}$ corresponds to the hyperplane at infinity of the latter $\mathbb{P}^{n}$.

Now we ask
Ouestion 3.7. Assume that $\tau_{1}, \ldots,{ }^{\top}{ }_{m} \varepsilon J *(n, k)$,
$\lambda_{1}, \ldots, \lambda_{\mathrm{m}-1} \varepsilon \mathrm{~A}(\mathrm{n}, \mathrm{k}), \lambda_{\mathrm{i}} \notin \mathrm{A}(\mathrm{n}, \mathrm{k})$ for any i and that every $\lambda_{j}$ do not fix the point $(1,0, \ldots, 0)$. Let $T_{i}$ be the graph of the birational correspondence induced by $\tau_{i} \lambda_{i}{ }^{\top}{ }_{n+1} \cdots{ }^{\lambda}{ }_{m-1}{ }^{\top}{ }_{m}$. Does $T_{i-1}$ dominates $\mathrm{T}_{\mathrm{i}}$ for every $\mathrm{i}=2, \ldots, \mathrm{~m}$ ?

If this question, or something similar, has an affirmative answer, we would be able to prove not only an adaption of Theorem 3.3 in Part 1 for the group $J(n, k) \vee A(n, k)(c f$. Lemma 3.3), but also Conjecture 3.1. Another base is the following confecture :*)

Conjecture 3.8. Assuem that $v \varepsilon J(3, k) \vee A(3, k), \vee \notin A(3, k)$.

Let the highest degree parts of $\nu \mathrm{x}_{1}, \nu \mathrm{x}_{2}, v \mathrm{x}_{3}$ are $\mathrm{g}_{1}, \mathrm{~g}_{2}, \mathrm{~g}_{3}$ respectively. Then, either there is one of the $g_{i}$ which is a polynomial of the other two, or, there are two of these $g_{i}$ which are powers of the same form.

Note that our example $\sigma$ in § 2.1 as an element of Aut $_{K} K[x, y, z]$ does not satisfy the condition in the conclusion of the conjecture. Therefore, if this Conjecture 3.8 has an affirmative answer, then so

[^0]does Conjecture 3.1.

One difficulty in proving Conjecture 3.8 lies on the fact that there is an injection $\eta: k[x] \rightarrow k[x](n=3)$ such that the highest degree parts of $n x_{i}(i=1,2,3)$ satisfy the condition in the conjecture, and on the other hand, for a suitable choice of $\tau \varepsilon J(3, k)$, the highest degree parts of $\tau n x_{i} \quad(i=1,2,3)$ do not satisfy the condition.

By the way, we prove :

Proposition 3.9. Assume that $k$ is a field, $n=3, \sigma \varepsilon A_{k} k[x]$, and that $\operatorname{deg} \sigma x_{i} \leq 2$, $\operatorname{deg} \sigma^{-1} x_{i} \leq 2$ for every $i=1,2,3$. Then $\sigma=\lambda \tau \lambda^{\prime}$ with $\lambda, \lambda^{\prime} \in A(3, k), \tau \varepsilon J(3, k)$.

Proof. Considering elements of the form $\lambda \sigma$ with $\lambda \varepsilon \mathrm{A}(3, \mathrm{k})$, we may assume that $\sigma x_{i}=x_{i}+f_{i}$ for each $i$, where $f_{i}$ is a homogeneous form of degree 2 . Then $\sigma^{-1} x_{i}=x_{i}+g_{i}$ with a homogeneous form $g_{i}$ of degree 2 , by virtue of our assumption.

$$
x_{i}=\sigma^{-1} \sigma x_{i}=\sigma^{-1}\left(x_{i}+f_{i}\right)=x_{i}+g_{i}+f_{i}\left(x_{1}+g_{1}, x_{2}+g_{2}, x_{3}+g_{3}\right)
$$

Compairing degree 2 parts, we have $g_{i}=-f_{i}\left(x_{1}, x_{2}, x_{3}\right)$;
From degree 4 parts, we have $\quad 0=f_{i}\left(g_{1}, g_{2}, g_{3}\right)$.
If the locus of $\left(g_{1}, g_{2}, g_{3}\right)$ in the projective plane $\mathbb{P}^{2}$ is dense in $\mathbb{P}^{2}$, then $f_{i}=0$ by the second equality, hence $g_{i}=0$ by the first
equality, which is a contradiction. If the locus of $\left(g_{1}, g_{2}, g_{3}\right)$ is a curve $C$, then all of $f_{1}, f_{2}, f_{3}$ must be a multiple of the defining polynomial $F$ for the curve $C$. Hence, either $C$ is a conic and $f_{i}=c_{i}{ }^{F}$ with $c_{i} \varepsilon k$, or $C$ is a line and $f_{i}=h_{i}{ }^{F}$ with linear forms $h_{i}$. The former case gives us a contradiction because of the equality $g_{i}=-f_{i}$. Thus the locus $C$ is a line, which means that $g_{1}, g_{2}, g_{3}$ are linearly dependent. Therefore, using a linear transformation, we may assume that $g_{3}=0$. In this case $g_{1}, g_{2}$ are linearly independent and $F=X_{3}$. Then, considering the degree 3 parts, we have $0=x_{3} h_{i}\left(g_{1}, g_{2}, 0\right)$ (for $i=1,2)$. Since the locus of $\left(g_{1}, g_{2}, 0\right)$ is the line $C$ defined by $x_{3}=0$, we see that $h_{i}$ is a multiple of $x_{3}$. Thus $f_{1}=c_{1} x_{3}{ }^{2}$, $f_{2}=c_{2} x_{3}{ }^{2}$, which contradicts our assumption that $g_{1}, g_{2}$ are linearly independent. Thus the locus of $\left(g_{1}, g_{2}, g_{3}\right)$ must be a point, which means that $g_{1}=c_{1} G\left(c_{i} \in k\right)$ with a fixed quadratic form $G$. Then using a linear transformation, we may assume that $g_{2}=g_{3}=0$. Then the remainder of the proof is obtained by the following

Lemma 3.10. Assume that $\sigma \varepsilon \operatorname{Aut}_{k} k[x]$. If $\sigma x_{i}=x_{i}$ for every $i \leq 2$, then $\sigma \in J(n, k)$.

Proof is similar to the one for Lemma 1.1 in Part 1.
2.4 One more question.

We like ask here a question. Consider the case where $k$ is a field
and $n \geq 1$. If $n=1$ or 2 , then we see the following proposition by our observation made in Part 0, Part 1 :

Proposition 4.1. If $K$ is a field and if $n \leq 2$, then $\operatorname{Aut}_{k} k[x]$ is generated by $A(n, k)$ and $A u t_{k\left[x_{1}\right]} k[x]$.

Therefore we ask :

Question 4.2. Assume that $k$ is a field and $n \geq 3$. Is

Aut $_{k} k[x]$ generated by $A(n, k)$ and $A u t_{k\left[x_{1}\right]} k[x]$ ?
We note here that our assumption that $k$ is a field is important.

Indeed, our example in § 2.1 shows that the question has negative answer
if $k$ is an integral domain which is not a field (in the case $n=2$ ).
