# A Quantitave Version of the Schneider-Lang Theorem

By Noriko HIRATA (平田 典子)
Ochanomizu Univ.

#### §1. Introduction

We begin with the result of Hermite and Lindemann which implies the transcendence of e and  $\pi$ . Secondly, we refer to the Gel'fond-Schneider theorem, that is the solution of the seventh problem of Hilbert, settled in 1934. Next, we state the Schneider-Lang theorem, and we show how this result contains the Hermite-Lindemann theorem and the Gel'fond-Schneider theorem. Finally, here, we give a quantitative version of the theorem of Schneider and Lang.

Let us recall the above theorems.

Theorem (Hermite-Lindemann). Let  $\alpha$  be a non-zero algebraic number, then  $e^{\alpha}$  is a transcendental number.

Theorem (Gel'fond-Schneider). Let  $\alpha$  and  $\beta$  be algebraic numbers. Assume that  $\alpha \neq 0$ ,  $\alpha \neq 1$ , and that  $\beta$  is not rational.

Let log  $\alpha$  be any determination of the logarithm of  $\alpha$ . Then  $\alpha^\beta = \exp(\beta \log \alpha) \text{ is a transcendental number.}$ 

Important examples of numbers whose transcendence follows from these theorems are  $e^{\pi}$  and  $2^{\sqrt{2}}$ . Gel'fond's proof was based on the following ideas. If we suppose  $\log \alpha_2 = \beta \log \alpha_1$  with an irrational algebraic number  $\beta$  and algebraic numbers  $\alpha_1, \alpha_2$  (# 0, 1), then the two functions  $\alpha_1^z = e^{z \log \alpha_1}$  and  $\alpha_2^z = e^{z \log \alpha_2} = e^{z \log \alpha_1}$  take algebraic values at all integer points. Moreover, their derivatives with respect to the derivation operator  $\frac{1}{\log \alpha_1} \frac{d}{dz}$  at all integer points are also algebraic.

We can construct a non-zero polynomial P  $\in \mathbf{Z}[X_1,X_2]$  such that the function  $F(z) = P(\alpha_1^Z,\alpha_2^Z)$  vanishes at several integer points with a high order, and after that we show that F has more and more zeroes, finally,  $F \equiv 0$ , which is a contadiction to the algebraic independence of the two functions  $\alpha_1^Z$  and  $\alpha_2^Z$  because  $\beta$  is not rational.

We now mention the following general result.

Theorem (Schneider-Lang). Let K be a number field and let  $f_1,\cdots,f_h$  be meromorphic functions. We assume that  $f_1$  and  $f_2$  are algebraically independent over  $\mathbf{Q}$ , and of order at most

The order of an entire function f is

$$\lim_{R\to\infty} \sup \frac{\log \log |f|_R}{\log R}$$

and if a meromorphic function can be written as quotient of two entire functions of order  $\leq \rho$ , then it is called a function of order  $\leq \rho$ .

We obtain the theorem of Hermite-Lindemann as a corollary to this theorem by setting K =  $\mathbf{Q}(\alpha, \mathbf{e}^{\alpha})$ , h = 2,  $\mathbf{f}_1(z) = z$ ,  $\mathbf{f}_2(z) = \mathbf{e}^z$ ,  $\rho_1 = 0$ ,  $\rho_2 = 1$ . Secondly, when K =  $\mathbf{Q}(\alpha_1, \alpha_2, \beta)$ , h = 2,  $\mathbf{f}_1(z) = \mathbf{e}^z$ ,  $\mathbf{f}_2(z) = \mathbf{e}^{\beta z}$ ,  $\rho_1 = \rho_2 = 1$ , we deduce Gel'fond-Schneider theorem from this theorem immediately.

This upper bound  $(\rho_1 + \rho_2)[K:\mathbf{Q}]$  is sometimes the best possible (the functions z and  $\exp(z(z-1)\cdots(z-k+1))$  take integer values at k points).

The Gel'fond-Schneider theorem shows that if we take any distinct complex numbers  $w_1, \cdots, w_m$  with  $m > (\rho_1 + \rho_2)[K:\mathbf{Q}]$  then at least one value  $f_i(w_\mu)$  ( $1 \le i \le h$ ,  $1 \le \mu \le m$ ) doesn't belong to K. We deduce from this property that the sum

$$\sum_{i=1}^{h} \sum_{\mu=1}^{m} |f_i(w_{\mu}) - \alpha_{i\mu}|$$

is not zero where  $\alpha_{\mbox{i}\mu}$  are any algebraic numbers in K. Here, we give a lower estimate to this sum in terms of heights  $\mbox{H}(\alpha_{\mbox{i}\mu})$  of  $^{\alpha}\mbox{i}_{\mbox{u}}$  .

## §2. Statement of result

Theorem. Let K be a number field and let  $f_1, \dots, f_h$  be meromorphic functions. We assume that  $f_1$  and  $f_2$  are algebraically independent over  $\mathbf{Q}$ , and of order at most  $\rho_1, \rho_2$  respectively. We assume further that the ring  $\mathrm{K}[f_1, \dots, f_h]$  is stable under the derivation  $\frac{\mathrm{d}}{\mathrm{d}z}$ . We take any distinct complex numbers  $w_1, \dots, w_m$  which are not poles of  $f_1, \dots, f_h$  with  $m > (\rho_1 + \rho_2)[k:\mathbf{Q}]$  and  $w_1 = 0$ . Suppose also that  $f_i(0) \in \mathrm{K}(1 \le i \le h)$ . We denote by d the maximum of the total degrees of  $A_i$  where  $\frac{\mathrm{d}}{\mathrm{d}z} f_i = A_i(f_1, \dots, f_h)$ ,  $A_i \in \mathrm{K}[X_1, \dots, X_h]$  for  $1 \le i \le h$ . Put  $\delta = [\mathrm{K}:\mathbf{Q}]$  and

$$\kappa_0 = \frac{2^{h}(d-1)(\delta-1)(\rho_1+\rho_2)}{m-\delta(\rho_1+\rho_2)}.$$

Then for all K > K0, there exists an explicit number  $H_0$  such that if we take any algebraic numbers  $\alpha_{i\mu}$  (1  $\leq$  i  $\leq$  h, 1  $\leq$   $\mu$   $\leq$  m) in K, then we have

$$\begin{array}{ccc}
h & m \\
\sum & \sum \\
i=1 & \mu=1
\end{array} | f_i(w_{\mu}) - \alpha_{i\mu}| \ge \exp(-H^{\kappa})$$

where  $H = \max (H(\alpha_{iu}), H_0)$ .

**Remark.** We deduce from this theorem the following result which is mentioned by D.W.Masser in [M]: For any  $\epsilon > 0$  there exists a number  $m_0(\epsilon)$  such that for all  $m > m_0(\epsilon)$  we have

$$\sum_{i=1}^{h} \sum_{\mu=1}^{m} |f_i(w_{\mu}) - \alpha_{i\mu}| \ge \exp(-H^{\epsilon}).$$

The above theorem gives to Masser's  $\mathbf{m}_0(\epsilon)$  an explicit value, namely

$$m_0(\varepsilon) = \frac{2^h(d-1)(\delta-1)(\rho_1+\rho_2)}{\varepsilon} + \delta(\rho_1 + \rho_2).$$

### §3. Outline of the proof

We assume

(1) 
$$\sum_{i=1}^{h} \sum_{\mu=1}^{m} |f_i(w_{\mu}) - \alpha_{i\mu}| < \exp(-H^{\kappa})$$

and we shall get a contradiction. Let  $\ell$  be a sufficiently large integer. Without loss of generality we may assume H >>  $\mathrm{H}_0$  where  $\mathrm{H}_0$  is sufficiently large with respect to  $\ell$ .

$$U = H^{\kappa}$$
,  $T = H^{\kappa/2}^{h}$ ,  $L_1 = \ell T^{\rho_2/(\rho_1 + \rho_2)}$ ,  $L_2 = \ell T^{\rho_1/(\rho_1 + \rho_2)}$ .

**Step 1.** Construction of algebraic numbers  $\alpha(\lambda_1, \lambda_2, t, \mu)$ 

We can write

$$\frac{d^{t}}{dz^{t}} f_{1}^{\lambda_{1}} f_{2}^{\lambda_{2}} = Q_{\lambda_{1}, \lambda_{2}, t}(f_{1}, \dots, f_{h})$$

where  $Q_{\lambda_1,\lambda_2,t}$  is a polynomial with coefficients in K (0 $\leq \lambda_1$ <L<sub>1</sub>,

 $0 \le \lambda_2 < L_2$ ,  $0 \le t$ ), using the differential equations of  $f_i$  ( $1 \le i \le h$ ). Define

$$\alpha(\lambda_1, \lambda_2, t, \mu) = Q_{\lambda_1, \lambda_2, t}(\alpha_{1\mu}, \dots, \alpha_{h\mu}).$$

Then for 0≤t<T we get

$$\left|\frac{\mathrm{d}^{\mathsf{t}}}{\mathrm{d}z^{\mathsf{t}}} f_{1}^{\lambda_{1}} f_{2}^{\lambda_{2}}(w_{\mu}) - \alpha(\lambda_{1}, \lambda_{2}, \mathsf{t}, \mu)\right| < e^{-\frac{1}{2}U}$$

by the hypothesis (1).

## Step 2. Construction of an auxiliary function F

We consider the linear system

$$\sum_{\lambda_1, \lambda_2} p_{\lambda_1 \lambda_2} \alpha(\lambda_1, \lambda_2, t, \mu) = 0$$

for  $0 \le \lambda_1 < L_1$ ,  $0 \le \lambda_2 < L_2$ ,  $0 \le t < T$ ,  $1 \le \mu \le m$  of Tm equations in  $L_1L_2$  unknowns  $p_{\lambda_1\lambda_2}$ . This system has coefficients

in K and we get a non-trivial solution by the choice of  $\mathbf{L}_1$  and  $\mathbf{L}_2$ . Siegel's lemma gives that

$$\max_{\substack{0 \leq \lambda_1 \leq L_1 \\ 0 \leq \lambda_2 \leq L_2}} \log |p_{\lambda_1 \lambda_2}| < \frac{1}{\ell} T \log T + O(T).$$

Put

$$F = \sum_{\lambda_1, \lambda_2} p_{\lambda_1 \lambda_2} f_1^{\lambda_1} f_2^{\lambda_2}(z).$$

Step 3. Upper bound of the order of zeroes at the origin

Liouville's theorem implies that  $f_i(0) = \alpha_{i1}$  for all  $1 \le i$   $\le h$  because  $f_i(0)$  is algebraic. From this, we have

$$\frac{d^{t}}{dz^{t}} F(0) = \sum_{\lambda_{1}, \lambda_{2}} \sum_{\lambda_{1}, \lambda_{2}} \alpha(\lambda_{1}, \lambda_{2}, t, 1) = 0$$

for  $0 \le t < T$ , that means ord<sub>z=0</sub>  $F \ge T$ .

Let  $\textbf{T}_1$  be the smallest integer such that there exists 1  $\leq \mu_0 \leq$  m with

$$\sum_{\lambda_1,\lambda_2} p_{\lambda_1\lambda_2} \alpha(\lambda_1,\lambda_2,T_1,\mu_0) \neq 0.$$

By the algebraic independence of  $f_1$  and  $f_2$ , we can deduce from the theorem of Brownawell and Masser ([B-M])

$$\operatorname{ord}_{z=0} F \leq (d\ell^2 T)^{2^{h-1}},$$

so we have

$$T_1 \le (dl^2T)^{2^{h-1}}$$
.

### Step 4. Contradiction

We can estimate the derivatives of F:

$$\log \left| \frac{d^t}{dz^t} F(w_{\mu}) \right| < -\frac{1}{3}U$$

for  $0 \le t < T_1$ ,  $1 \le \mu \le m$ .

Then using the residue formula, we have

$$\log |F|_{r} \le (\frac{1}{\ell} - \frac{m}{\rho_{1} + \rho_{2}})T_{1} \log T_{1} + O(T_{1})$$

for 
$$r = 1 + \max_{1 \le \mu \le m} |w_{\mu}|$$
.

Put

$$\gamma = \sum_{\lambda_1, \lambda_2} p_{\lambda_1 \lambda_2} \alpha(\lambda_1, \lambda_2, T_1, \mu_0)$$

which is not zero. As above we can estimate the  $T_1$ th derivative of f:

$$\log \left| \frac{d^{T_1}}{dz^{T_1}} F(w_{\mu_0}) - \gamma \right| < -\frac{1}{3}U.$$

Then we get

$$|\gamma| \leq \left| \frac{d^{T_1}}{dz^{T_1}} F(w_{\mu_0}) \right| + \left| \frac{d^{T_1}}{dz^{T_1}} F(w_{\mu_0}) - \gamma \right|$$

$$\leq T_1^{T_1} |F|_r + e^{-\frac{1}{3}U},$$

hence we obtain

$$\log |\gamma| \le (1 + \frac{1}{\ell} - \frac{m}{\rho_1 + \rho_2})T_1 \log T_1 + O(T_1).$$

However we get by the size inequality

$$\log |\gamma| \ge -(\delta - 1)(1 + \frac{1}{\ell} + \frac{2^{h}(d-1)}{\kappa})T_{1} \log T_{1} + O(T_{1})$$

then we arrive at the contradiction:

$$\kappa \leq \kappa_0 = \frac{2^{h}(d-1)(\delta-1)(\rho_1+\rho_2)}{m-\delta(\rho_1+\rho_2)}.$$
