Existence of an unramified cyclic extension and congruence conditions

Makoto Ishida (石田 方意)
(Tokyo Metropolitan University)

Let K be an algebraic number field of odd prime degree  $\ell$ . Then the following two facts are known.

1) The prime  $\ell$  is totally ramified in K if and only if there exists a primitive element  $\pi$  of K ( $K = \Omega(\pi)$ ) having the minimal polynomial f(X) of Eisenstein type with respect to  $\ell$ , i.e.

$$f(X) = X^{\ell} + a_1 X^{\ell-1} + a_2 X^{\ell-2} + \dots + a_{\ell} \in \mathbf{Z}[X],$$
where  $a_1 \equiv a_2 \equiv \dots \equiv a_{\ell} \equiv 0 \pmod{\ell}$ 
and  $a_{\ell} \not\equiv 0 \pmod{\ell^2}$ .

Let  $k^+$  be the unique (real) subfield, of degree  $\ell$ , of the  $\ell^2$ -th cyclotomic field.

2) In the case 1),  $L = k^{+}K$  is an unramified (cyclic) extension over K if and only if we have

$$a_1 + a_{\ell} \equiv a_2 \equiv \dots \equiv a_{\ell-1} \equiv 0 \pmod{\ell^2}$$
.

We exclude the special case  $K = k^+$ . So, in the following, we may suppose  $K \neq k^+$  and  $[L:K] = \ell$ . Of course, we may also suppose that K is real.

Now our problem in the case 2) is as follows :

Is there an unramified cyclic extension M, of degree  $\ell^2$ , over K, containing  $L = k^+K$ ? More precisely, are there any higher congruence conditions on the coefficients  $a_1, a_2, \ldots, a_\ell$  of f(X), which ensure the existence of such an extension M of K?

I. Under the congruence conditions in 1) and 2), our first conclusion is:

If  $a_{\ell} \neq \ell d^{\ell} \pmod{\ell^3}$  for any  $d \in \mathbb{Z}$ , then there is no unramified cyclic extension, of degree  $\ell^2$ , over K, containing  $L = k^+ K$ .

In fact, let  $\ell$  be the prime ideal in K dividing  $\ell$  and we have  $(\pi)=\ell\mathcal{L}$  with  $(\ell,\mathcal{E})=1.$  The ideal class group  $C_K$  of K has the subgroup

 $G_{\ell} = \left\{ \begin{array}{c|c} \operatorname{Cl}(\ell) & (\ell,\ell) = 1 \text{ and } \operatorname{N}(\ell^{\ell-1}) \equiv 1 \pmod{\ell^2} \end{array} \right\}$  of index  $\ell$ , which corresponds to the abelian extension L in the sense of class field theory. Then it is proved

$$a_{\ell} \neq \ell d^{\ell} \pmod{\ell^3}$$
 for any  $d \in \mathbb{Z}$ 

$$\iff C1(\ell)^{-1} = C1(\ell) \notin G_{\ell}$$

$$\iff C_{K} = \langle C1(\ell) \rangle G_{\ell}.$$

Then the assertion easily follows.

Therefore, in consideration of our problem, we may suppose that we have  $a_{\ell} \equiv \ell d^{\ell} \pmod{\ell^3}$  with some  $d \in \mathbb{Z}$ . Then, replacing  $\pi$  by  $c\pi$  with  $c \notin \mathbb{Z}$  such that  $cd \equiv 1 \pmod{\ell^2}$ , we may assume that we have

$$a_{\ell} \equiv \ell \pmod{\ell^3}$$
.

II. From now on, we treat the cubic case i.e. l = 3. Notations:

 $\zeta$  = a primitive 3rd root of unity,  $\eta$  = a primitive 9-th root of unity,  $k = Q(\zeta) = Q(\sqrt{-3})$ , K' = kK, L' = kL, so  $L' = kk^+K = K(\eta) = K'(\eta) = K'(\sqrt[3]{\zeta})$ ,  $\zeta'$  = the prime ideal in K', dividing 3,

so (3) = 
$$\zeta^{6}$$
,  $\zeta^{2}$  |  $\pi$  and  $(1-\zeta) = \zeta^{3}$ .

- 1°. As preliminaries, we have the following two assertions.
- (a) Algebraic aspect. By Kummer theory, for any  $\alpha \in K'$   $(\alpha \neq 0)$ ,  $M' = L'(^3\sqrt{\eta\alpha}) = K'(^3\sqrt{\eta\alpha})$  is a cyclic extension, of degree 9, over K'. (Conversely, every cyclic extension, of degree 9, over K', containing L', is obtained in this way.) Moreover if we have

(\*) 
$$\alpha \alpha^{J} = \gamma^{3}$$
 with  $\gamma \in K'$ ,

(J denotes the complex conjugation)

then M' is an abelian extension, of degree 18, over K and the fixed subfield M by J is a cyclic extension, of degree 9, over K, containing  $L = k^+K$ .

- (b) Arithmetic aspect. As L' is unramified over K', the unramifiedness of M over K is equivalent to that of M' over L'. Then, by the ramification theory in Kummer extensions, it is also equivalent, under the condition  $(\alpha, \ell') = 1$ , to the two facts
  - (1) the principal ideal  $(\alpha)$  is the cube of an ideal in L'.
  - (2)  $\eta\alpha$  is congruent to the cube of an integer in L' modulo  $\chi'^9$  for any prime divisors  $\chi'$  of  $\chi'$  in L'.

Of course, we can easily modify these assertions for the case of arbitrary odd prime \mathbb{l}.

2°. Now we assume that the following congruence conditions are satisfied:

$$\begin{cases} a_3 \equiv 3 \pmod{3^3} & (\text{as remarked in I}) \\ \text{i.e. } a_3 = 3b \pmod{5^2}, & b \equiv 1 \pmod{3^2}), \\ a_1 \equiv -a_3 = -3b \pmod{3^3}, \\ a_2 \equiv 0 \pmod{3^3}. \end{cases}$$

We put  $\omega=b(1-\zeta)/\pi$  and  $\varepsilon=1-\omega$ , which are integers in K' such that  $\ell'\parallel\omega$  and  $\ell'\not\parallel\varepsilon$ .

Then, under the above conditions, it is proved that we have

$$(\varepsilon^{J})^3 - \varepsilon^3 \zeta \equiv 0 \pmod{\ell^{15}}$$
.

So we have

 $\zeta$  = the cube of an integer in K' (mod  $\mathcal{L}^{10}$ ), which implies that  $\mathcal{L}'$  is completely decomposed in L' = K'( $\sqrt[3]{\zeta}$ ):  $\mathcal{L}' = \mathcal{L}_1'\mathcal{L}_2'\mathcal{L}_3'$ , Moreover, for each prime ideal  $\mathcal{L}_1'$ , we see that

 $(\epsilon^{J} - \eta \epsilon) (\epsilon^{J} - \eta \epsilon \zeta) (\epsilon^{J} - \eta \epsilon \zeta^{2}) \equiv 0 \pmod {\mathcal{L}_{i}}^{15}).$  Investigating the exponent of  $\mathcal{L}_{i}$  in each factor of the lefthand side, we have

$$\eta \epsilon \zeta^{j} \equiv \epsilon^{J} \pmod{(\chi_{i}^{9})}$$
 with some  $j = j(i)$ .

Hence our second conclusion follows:

We have

$$\eta \epsilon (\epsilon^{J})^{2} \equiv \underline{\text{the cube of an integer in}} \quad L'$$

$$(\text{mod } \mathcal{L}_{i})^{9}) \quad (i=1,2,3)$$

and

$$(\varepsilon(\varepsilon^{J})^{2}) (\varepsilon(\varepsilon^{J})^{2})^{J} = (\varepsilon\varepsilon^{J})^{3}.$$

(That is,  $\alpha = \varepsilon(\varepsilon^{J})^2$  satisfies the conditions (\*) in (a) and (2) in (b).)

3°. Consequently, by considering the extension M' = L'( $^3\sqrt{\eta\epsilon(\epsilon^J)^2}$ ) of K, our third conclusion is:

If the principal ideal  $(\epsilon(\epsilon^{J})^{2})$  is the cube of an ideal in L', then there exists an unramified cyclic extension M, of degree 9, over K, containing  $L = k^{+}K$ .

Here we note that, for an integer  $\delta$  in K' such that

$$\delta \equiv \epsilon = 1 - \omega \pmod{\ell^9}$$
,

we have the similar conclusion for the extension  $L'(\sqrt[3]{\eta\delta(\delta^J)^2})$ .

 $4^{\circ}$  . As for the assumption in the third conclusion, we can show that  $\epsilon$  is a unit in K' if and only if

$$N_{K'/k}(\varepsilon) = \pm 1 \text{ or } \pm \zeta \text{ or } \pm \zeta^2$$
,

and so if and only if  $(N_{K'/k}(\epsilon) = \zeta$  i.e.)

$$a_3 = 3b$$
,  $a_1 = -3b$ ,  $a_2 = 3(b^2-1)$   
(b = 1 (mod 3<sup>2</sup>))

(and in this case, our extension M exists).

In this special case, the minimal polynomial of  $\pi$ -b is given by  $X^3 - 3X + b^3$  and the discriminant is equal to  $-27(b^6-4)$ . We note that the norm  $N_{K'/K}(\epsilon)$  of the unit  $\epsilon$  is of course a unit of K and we have  $-(N_{K'/K}(\epsilon))^{-1} = b\pi + 1$ .

Hence we have the following assertion :

Let  $K = Q(\beta)$  be a cubic number field, where the minimal polynomial of  $\beta$  is

$$x^3 - 3x + b^3 \in Z[x]$$
  
with  $b \equiv 1 \pmod{3^2}$ .

Then  $1+b(\beta+b) = 1+b^2+b\beta$  is a unit of K. Moreover, K has an unramified cyclic extension of degree 9 (so the ideal class group of K contains a cyclic subgroup of order 9).

It is also shown that there are infinitely many cubic number fields  $K = Q(\beta)$ , which are obtained in the above way.

5°. Under the congruence conditions on  $a_1$ ,  $a_2$ ,  $a_3$  as in 2°, we investigate the  $\omega$ -adic expansions of several integers in K' and L', where  $\omega = b(1-\zeta)/\pi$  ( $f' \| \omega$ ). Let  $O_K$ , and  $O_L$ , be the rings of integers in K' and L' respectively. Since we have

(3) = 
$$\mathcal{L}^{106}$$
 in K' and  $\mathcal{L}' = \mathcal{L}_1'\mathcal{L}_2'\mathcal{L}_3'$  in L',

we can take  $\{0,1,-1\}$  as a representative system of the residue fields  $0_{K'}/\ell'$  and  $0_{L'}/\ell_i'$ .

Then, after cumbersome calculations, we have

$$\begin{cases}
-3 \equiv \omega^{6} \\
\pi \equiv \omega^{2} + \omega^{5} - \omega^{6} - \omega^{7} - \omega^{8} - \omega^{9} \\
\zeta \equiv 1 - \omega^{3} - \omega^{6} + \omega^{9}
\end{cases} \pmod{\mathcal{L}^{10}};$$

especially we have

$$\zeta \equiv (1 - \omega - \omega^2)^3 \pmod{\lfloor 10}$$

(see 2°).

We fix one of  $\mathcal{L}_i$ 's: e.g.  $\mathcal{L}' = \mathcal{L}_1'$ . Then, by a suitable choice of  $\eta$  (a primitive 9-th root of unity), we have

$$\eta \equiv 1 - \omega - \omega^2 - \omega^3 + \omega^7 \pmod{2^9}.$$

As  $\omega^{J} = \omega (1+\zeta) \equiv -\omega - \omega^{4} + \omega^{7} + \omega^{8} \pmod{\zeta^{19}}$ , we see  $\eta (1-\omega) \equiv 1 + \omega + \omega^{4} - \omega^{7} - \omega^{8}$  $\equiv 1-\omega^{J} \pmod{\zeta^{19}}.$ 

Consequently, putting  $\varepsilon = 1-\omega$ , we have

$$\eta \varepsilon \equiv \varepsilon^{J} \pmod{\mathcal{L}^{9}}$$
i.e.  $\eta \varepsilon (\varepsilon^{J})^{2} \equiv (\varepsilon^{J})^{3} \pmod{\mathcal{L}^{9}}$ .

For another  $\mathcal{L}_{i}$ ' (i=2,3), we have  $\mathcal{L}_{i}$ ' =  $\mathcal{L}^{\tau}$  with some  $\tau \in Gal(L'/K')$  and, as  $\eta^{\tau} = \eta \zeta^{j}$ ,

$$\eta \varepsilon (\varepsilon^{J})^{2} \equiv (\varepsilon^{J})^{3} \zeta^{-j}$$

$$\equiv (\varepsilon^{J} (1 - \omega - \omega^{2})^{-j})^{3} \pmod{\mathcal{L}_{i}^{9}}.$$

These are the congruences obtained in  $2^{\circ}$ .

Finally, we add some remærks in local aspect. We are interested in seeking all  $\alpha \in O_K$ , such that

$$\eta \alpha \equiv \alpha^{J} \beta^{3} \pmod{\mathcal{L}^{9}}$$
 with  $\beta \in O_{K'}$ ,

because this congruence implies

$$\eta \alpha (\alpha^{J})^{2} \equiv (\alpha^{J} \beta)^{3} \pmod{\mathcal{L}^{9}}$$
and 
$$(\alpha (\alpha^{J})^{2}) (\alpha (\alpha^{J})^{2})^{J} = (\alpha \alpha^{J})^{3},$$

that is,  $\alpha(\alpha^J)^2$  satisfies the conditions (\*) in (a) and (2) in (b).

If 
$$\eta \alpha \equiv \alpha^{J} \beta^{3} \pmod{\mathcal{L}^{9}}$$
, then we have  $\alpha/\epsilon \equiv (\alpha/\epsilon)^{J} \beta^{3} \pmod{\mathcal{L}^{9}}$ .

It is proved that, for any  $\gamma \in O_{K'}$  ( $\gamma \equiv 1 \pmod{\ell'}$ ), we have  $\gamma \equiv \gamma^{J} \beta^{3} \quad \text{i.e.} \quad \alpha \equiv \epsilon \gamma \qquad (\text{mod } {\ell'}^{9})$ 

if and only if

$$\gamma \equiv \lambda \mu^3 \pmod{\ell^9}$$
,

where  $\lambda, \mu \in O_{K'}$  ( $\lambda, \mu \equiv 1 \pmod{\ell'}$ ) such that  $\lambda \equiv \lambda^{J} \pmod{\ell'}$ .

Hence, for  $\alpha \in O_{K'}$  ( $\alpha \equiv 1 \pmod{\ell'}$ ) such that  $\alpha \equiv \epsilon \gamma$  i.e.  $\equiv \epsilon \lambda \mu^3 \pmod{\ell'}$ ,

if the principal ideal  $(\alpha(\alpha^J)^2)$  is the cube of an ideal in L', then the extension M' = L'( $^3\sqrt{\eta\alpha(\alpha^J)^2}$ ) has the subfield M, which is an unramified cyclic extension, of degree 9, over K, containing L =  $k^+K$ .

We note that, as  $\varepsilon = 1-\omega$  and  $\gamma \equiv 1 \pmod {\ell^2}$ , we have  $\alpha \equiv \varepsilon \gamma \equiv 1-\omega \pmod {\ell^2}$ .

Among  $3^7$  classes of  $0_{K'}/\mathcal{L}^{'9}$ , containing an integer  $\approx 1-\omega$  (mod  $\mathcal{L}^{'2}$ ), there are exactly  $3^5$  classes, containing some  $\epsilon \gamma$  as above.
