1, Introduction

Our purposes are to construct a programing language which is fit a model theory in mathematics and to show that its effectiveness. For this, we suppose a little knowledge on a model theory in order to read this paper (see, for example, [1]). Since we are concerned with classical analysis, it is sufficent to consider it in supper-structure U constructed by a real field R . Defining ordinarily a surjection i from a set $\mathcal{S}$ made up by finite sequences of alphabet A to the supper-structure U , we construct a formal language by a usual way. In this paper we try to regard the formal language as the programing language.

For this, we should show the table of the surjection $i: \mathcal{S} \rightarrow U$, which would be called the dictionary of U , in the section 2. Next we consider a little about "normal represetation of formular" in yhe section 3 and about " question and command", by which computer works effectively, in the section 4. In the section 5, we show an example of our program.

2. Dictionary of the supper-structure U

About the following words (i.e. elements of $\mathcal{S}$), we shall

explain:

a) R

:: R denotes a real field.

b) $\pm 0.a_1a_2a_3a_4a_5a_6 \cdot 10^{**n}$ (where n and a_k ($1 \leq k \leq 6$) are integers such that $0 \leq a_k \leq 9$, $-100 \leq n \leq 100$)

:: which denotes a floating point of order 6.

c) $\pm a_na_{n-1} \dots a_1a_0.b_0b_1 \dots b_m$ (where a_i and b_j ($0 \leq i, j \leq 5$) are integers such that $0 \leq a_i, b_j \leq 9$)

:: which denotes a fixed point.

d) $+, -, *, /, **, \sin, \cos, \tan, \exp, \log, \ln, \text{abs}$,

:: which denotes an ordinary arithmetic operator respectively.

e) $=, \leq, \geq$,

:: which denote an equality and inequalities

REMARK If R^n (n -dimensional Euclidean space), $\text{Mat}(m, n)$, etc are contained in this dictionary, it seems that our language is more powerful. But in this paper we do not mention about this extension.

3. Normal representation

For example, we consider the following formulars

$$(1) \quad x=1$$

$$(2) \quad x^2=1 \wedge x \geq 0 \quad (\text{ where } \wedge \text{ means "and" }).$$

These two formulars are equivalent, but it seems that the formular (1) is simpler than (2). This implies that a kind of formulars often have a simpler representation. In this section, we consider about this when x is a real number.

The formular

$$x = 0.a_1a_2a_3a_4a_5a_6 \cdot 10^n$$

means that the approximation of x is $0.a_1a_2a_3a_4a_5a_6 \cdot 10^n$.

And this formular is called an approximate normal representation of x and denoted by $ANR[x]$.

4. Question and Command

We can input the following question to computer

"WHAT IS $ANR[x]$? " (in abbreviation " $ANR[x]?$ ")

This means the question what is an approximate normal representation of x . And the question is effective when there have been already existed a formular $x=f(x_1, x_2, \dots, x_n)$ where f is a composed function of arithmetic operators in the section 2 ,d) and approximate normal representations of $x_1, x_2, \dots, x_n$ have been already known.

Although we should define a various commands, in this paper we borrow them in FORTRAN for convenience. And the representation's methods of formulars are refered in [2].

5. Example

Under these representations, we write the program in our language obtaining an approximation $2^{1/2}$ by the newton's method.

```

      DIMENSION X(20)
      X(1): X(1)=2.0
      WHAT IS ANR[X(1)]?
      DO 100 n=2,20
      X(n): X(n)=(X(n-1)**2+2.0)/2*X(n-1)
      WHAT IS ANR[X(n)] ?
      IF X(n-1)-X(n) .LT. 10.0**(-5) GOTO 200
100 CONTINUE

```

200 PRINT X(n)

STOP
