

Singularities of normal affine surfaces

宮西正宜 (阪大理)

(I) k : alg. closed field of char 0,

X : affine normal surface / k containing a cylinderlike open set $U \cong U_0 \times \mathbb{A}_k^1$ (U_0 : curve);
 X contains such a U if $\exists G_a$ -action on X .

d, e : positive integers s.t. $d > e$ and $(d, e) = 1$; $G = \mathbb{Z}/d\mathbb{Z} \cong \{d\text{-th roots of } 1\}$ which acts on $\mathbb{A}_k^2 = \text{Spec}(k[x, y])$ by $\zeta(x, y) = (\zeta x, \zeta^e y)$ for $\zeta \in G$; $T := \mathbb{A}_k^2/G$ with the image point Q of $(0, 0)$. $P \in X$ has a cyclic quotient singularity of type $(d, e) \iff \hat{\mathcal{O}}_{P, X} \cong \hat{\mathcal{O}}_{Q, T} \cong k[[x, y]]^G = k((x^d, \frac{y}{x^e})) \cap k[[x, y]]$. A cyclic quotient singular point P of X is a rational singular point, and if $\pi: \hat{X} \rightarrow X$ is the minimal resolution of P , $\pi^{-1}(P)$ has the following dual graph:

where the integers $\alpha_1, \dots, \alpha_r$ are obtained as

$$\frac{d}{e} = \alpha_1 - \frac{1}{\alpha_2 - \frac{1}{\alpha_3 - \frac{1}{\alpha_4 - \dots - \frac{1}{\alpha_r}}}}$$

Main Theorem. Let X be a normal affine surface $/k$ containing a cylinderlike open set U . Then we have:

(1) Every singularity of X is a cyclic quotient singularity.

(2) $X - U = \coprod_i C_i$, disjoint union of irred. components. C_i is a rational curve with only one place at ∞ passing through at most one singular point of X ; if $C_i \nrightarrow$ any singular point of X , $C_i \cong \mathbb{A}_k^1$; if C_i passes through a singular point P , the configuration of $\pi^{-1}(C_i)$ is:

(3) Every cyclic quotient singularity of type (d, e) is realized as a singular point of an affine normal surface containing a cylinderlike open set.

(II) Application to the Jacobian Problem

Recall the Jacobian Problem:

Let $\varphi: U := \mathbb{A}_k^2 \longrightarrow Y := \mathbb{A}_k^2$ be an étale morphism.

Is φ then an isomorphism?

Let $X :=$ normalization of Y in $k(U)$. Then

$$\begin{array}{ccc} U & \xrightarrow{\text{open}} & X \\ \varphi \searrow & & \swarrow \tilde{\varphi} \\ & Y & \end{array}$$

where $\tilde{\varphi}$ is a finite (ramified) covering and X is an affine normal surface containing a cylinderlike open set $U \cong \mathbb{A}_k^1 \times \mathbb{A}_k^1$. Thus, Main Theorem is applied to X .

Write $X - U = \coprod_i C_i$; $P_1, \dots, P_t$: all singular points of X (if at all). If $P_j \in$ some C_i , then $C_i \subset$ the ramification locus of $\tilde{\varphi}$.

Conjecture 1. (i) X is nonsingular ; (ii) the branch locus of $\tilde{\varphi}$ is a union of irred. components isomorphic to A_k^1 .

To prove Conjecture (1), it suffices to affirm :

Conjecture 2. Let $f, g \in k[[x, y]]^G \subseteq k[[x, y]]$, where $G = \mathbb{Z}/d\mathbb{Z}$ acts on $k[[x, y]]$ via $\zeta(x, y) = (\zeta x, \zeta^e y)$. Assume that $k[[x, y]]$ is a finite $k[[f, g]]$ -module. Then the ramification locus of $\text{Spec}(k[[x, y]]) \rightarrow \text{Spec}(k[[f, g]])$ has at least two irred. components (through the point $(0, 0)$), which are not transitive to each other by the action of G .

A topological version of Conjecture 2 is :

Conjecture 3. Let $L(3; d, e)$ be the 3-dim $\mathbb{C}$ lens space of type (d, e) . Then there are no finite ramified coverings $f: L(3; d, e) \rightarrow S^3$, which ramifies along a single knot.

Answer is No. (cf. F. Raymond, A. Fujiki).

(III) Proof of Main Theorem (Outline)

(1) Embed $X \subset V$ (= normal projective surface)

so that V is nonsingular along $V-X$, every irred. component of $V-X$ is nonsingular, and $V-X$ has only normal crossings as singularities.

Then, the projection $p: U \rightarrow U_0$ gives an irred. pencil Λ on V ; we may assume Λ has no base points because X is affine. Hence, $\exists$ a surjective morphism $\varphi: V \rightarrow C$ ($=$ nonsingular complete curve) such that:

- (i) $\varphi|_U = p$ with $U_0 \subset C$,
- (ii) general fibers F of φ are $\cong \mathbb{P}_k^1$
- (iii) $\exists$ irred. component S of $V-X$ s.t. $(S \cdot F) = 1$, i.e., S is a cross-section of φ .

(2) We may assume that U is nonsingular.

$P_1, \dots, P_t$: all singular points of X ; $\forall P_i \notin U$.

$\pi: W \rightarrow V$: minimal good resolution of $P_1, \dots, P_t$,

i.e., a) $W - \pi^{-1}\{P_1, \dots, P_t\} \xrightarrow{\sim} V - \{P_1, \dots, P_t\}$,

- b) Every irred. component of $\pi^{-1}(P_i)$ is nonsingular,
- c) $\pi^{-1}(P_i)$ has only normal crossings as singularities,
- d) $\exists$ no exceptional curves (of the first kind)

meeting at most two other components.

Let $L := \pi' \Lambda$ (the proper transform) and let $\psi := \varphi \cdot \pi : W \rightarrow C$; general fibers of ψ are $\cong \mathbb{P}_k^1$. Let P be one of $P_1, \dots, P_t$, let $F_0 := \varphi^{-1}(\varphi(P))$ and let $G_0 := \psi^{-1}(\varphi(P))$. Then $P \in F_0$ and $\pi^{-1}(P) \subset G_0$. Hence, every irred. component of $\pi^{-1}(P)$ is $\cong \mathbb{P}_k^1$, the dual graph of $\pi^{-1}(P)$ is a tree, and $\nexists$ no exceptional curves of the first kind meeting 3 or more other components. Hence, $\pi^{-1}(P) \nsubseteq$ exceptional curves of the first kind. Let $\rho := \varphi|_X : X \rightarrow C$ and let $Q := \rho(P)$. Then $\psi^{-1}(Q)$ is either $\mathbb{P}_k^1$ or a degenerate curve of $\mathbb{P}_k^1$. If $\psi^{-1}(Q)$ is a degenerate curve of $\mathbb{P}_k^1$, one irred. component of $\psi^{-1}(Q)$ is an exceptional curve of the first kind; after its contraction, $\psi^{-1}(Q)$ becomes $\mathbb{P}_k^1$ or a degenerate curve of $\mathbb{P}_k^1$; if it is still a degenerate curve, we can find an exceptional curve of the first kind among irred. components. After a succession of finitely many contractions, we get $\mathbb{P}_k^1$. This implies that the dual graph of a degenerate curve of $\mathbb{P}_k^1$ contains no circular chains.

(3) Claim : (i) Every irred. component of $P^{-1}(Q)$ is a connected component of $P^{-1}(Q)$.

(ii) Every irred. component of $P^{-1}(Q)$ is a rational curve with only one place at ∞ .

⊙ $\pi^{-1}(S) \cong S$, $\pi^{-1}(S) \subset W - \pi^{-1}(X) \cong V - X$ and $(\psi^{-1}(Q) \cdot \pi^{-1}(S)) = 1$. Then $\psi^{-1}(Q) - \psi^{-1}(Q) \cap \pi^{-1}(X) (\cong \varphi^{-1}(Q) - P^{-1}(Q))$ is connected.

$\downarrow \varphi$

Suppose an irred. component of $P^{-1}(Q)$ is not a connected component.

Then we have one of the configurations as shown below :

$\varphi^{-1}(Q)$ contains a cycle

or

2 or more components meet S

We have contradictions in both cases.

(4) Claim: C_i passes through at most one singular point.

☺ Let Y be an irred. component of $P^{-1}(Q)$ through P . Then $\exists$ ample divisor $D > 0$ s.t. $\text{Supp}(D) = V - X$ (cf. Goodman []). Hence, $\exists$ ample divisor $D' > 0$ s.t. $\text{Supp}(D') = (V - X) \cup (P^{-1}(Q) - Y)$. Replacing V by $V - \text{Supp}(D')$, we may assume that $P^{-1}(Q) = Y$. We may assume that $P^{-1}(Q) - Y$ contains no exceptional curves of the first kind. Suppose $P_1, \dots, P_s \in Y$. Let $\bar{Y}$ be the closure of $\pi'(Y)$ in W . Then, the configuration of $\psi^{-1}(Q)$ is one of the following:

Note that $\bar{Y}$ is the unique exceptional curve of the first kind in $\psi^{-1}(Q)$. By contracting $\bar{Y}$, we get contradictions in both cases.

(5) Claim : The dual graph of $\pi^{-1}(P)$ is a linear chain.

☹ We may assume that $P^{-1}(Q) = Y$. Suppose the dual graph is not a linear chain. Then $\pi^{-1}(P)$ has the configuration :

$\bar{Y}$ is the unique exceptional curve of the first kind in $\psi^{-1}(Q)$. Before contracting T_1 or T_2 , Z_l must become contractable after a succession τ of contractions. If $\tau(Z_l) \cap \tau(S) \neq \emptyset$ then $\sigma\tau(T_i) \cap \sigma\tau(S) \neq \emptyset$ for $i=1,2$, where σ is the contraction of $\tau(Z_l)$. If $\tau(Z_l) \cap \tau(S) = \emptyset$, $\exists$ irred. component C of $\tau(\psi^{-1}(Q))$ s.t. $C \neq \tau(Z_l)$, $\tau(T_i)$ ($i=1,2$) and $C \cap \tau(Z_l) \neq \emptyset$. Both cases lead to contradictions.

(6) Finally, note that if $\pi^{-1}(P)$ has the linear dual

graph, P is a cyclic quotient singular point.
